Executive summary

This System Characterization Report has been prepared on behalf of the City of Elizabeth (City) to meet certain conditions of the New Jersey Pollutant Discharge Elimination System (NJPDES) individual permit actions issued by the New Jersey Department of Environmental Protection (NJDEP) for Combined Sewer Overflow (CSO) control, with an effective date of July 1, 2015 (referred herein as the NJPDES CSO permits). As permittees of a hydraulically connected system, the City and the Joint Meeting of Essex and Union Counties (JMEUC or Joint Meeting) are cooperating and collaborating on the development of a Long Term Control Plan (LTCP) for CSO control per the permit conditions.

While the City and JMEUC are jointly working towards a single, coordinated LTCP to address the permit requirements, a separate System Characterization Report has been prepared by each permittee for their respective facilities, with the elements of each report having been coordinated and reviewed between the permittees. The City and JMEUC are communicating regularly, sharing information, and exchanging hydraulic models for appropriate characterization, monitoring, and integrated modeling of the hydraulically connected system.

The City and JMEUC are also members of a regional assembly of NJPDES CSO permittees, referred to as the NJ CSO Group. Members of this group consist of municipalities, sewerage authorities, and other entities that have been issued a NJPDES CSO permit and have agreed to work together to address common and overlapping areas for permit compliance. On behalf of the member permittees, the NJ CSO Group, with the Passaic Valley Sewerage Commission (PVSC) serving as the managing member, is providing shared services for these common elements of the CSO permits to avoid costly and inefficient duplication of efforts. These shared services encompass certain water quality monitoring and modeling work, such as ambient in-stream sampling and testing, baseline compliance monitoring, and pathogen receiving water quality modeling; production of CSO outfall identification signs; setup and operation of a CSO notification system website; and coordination with regulatory agencies on common issues for permit compliance.

Regulatory Context and Requirements

A combined sewer system (CSS) is a wastewater collection pipe network designed to carry sanitary sewage at all times, and also designed to collect and transport stormwater from streets and other sources, thus serving a combined purpose. During dry weather, a CSS conveys the sanitary sewage to the wastewater treatment plant. During wet weather, the combined flow of wastewater and storm runoff may exceed the available capacity or allowed flow to the downstream treatment works and by design, the excess flow is released through an outfall pipe or channel to a receiving stream. This excess flow is called a combined sewer overflow and CSO discharges during wet weather at designated outfall locations in the State of New Jersey are regulated by the NJDEP.

Combined sewers are prevalent throughout the northern, western, and southern sections of the City of Elizabeth, coinciding with its historical residential, industrial, and commercial development. All dry weather sewage from the City sewer system is conveyed to and treated at the JMEUC wastewater treatment plant (WWTP) in Elizabeth, NJ. The City of Elizabeth is a customer to JMEUC, not a member municipality, and is currently contractual limited to an 18 million gallon per day (mgd) maximum average daily flow and a 36 mgd maximum

instantaneous peak (wet weather) discharge from its main wastewater pumping station to the JMEUC treatment works.

In 2015, the New Jersey Department of Environmental Protection revoked prior authorizations related to combined sewer overflows under NJPDES Master General Permit No. NJ0105023 and issued individual permits to authorize CSO discharges. Discharges from the City of Elizabeth's 29 designated CSO locations are authorized and regulated by NJPDES Permit No. NJ0108782. While the Joint Meeting does not own or operate CSO discharge points, the downstream portion of the JMEUC trunk sewer system receives and conveys combined sewage from the City and the systems are hydraulically connected. As such, the NJDEP revoked and reissued the JMEUC individual Category "A" Permit No. NJ0024741 to incorporate the prior General Permit Authorization No. NJG0108740 and updated CSO permit requirements as part of the recent CSO permit actions.

These individual NJPDES permits contain provisions for the development of a CSO Long Term Control Plan in accordance with the National CSO Control Policy established by United States Environmental Protection Agency (EPA). A CSO LTCP involves a comprehensive study of the hydraulically connected sewer systems and the evaluation of alternatives for reducing CSO impacts to water quality. It investigates the hydrologic and hydraulic relationships between precipitation, conveyance, treatment capacity, and overflows and includes a feasibility study to evaluate the scope, costs, and performance of possible control alternatives for reducing the frequency and volume of CSO discharges. The planning approach consists of three major steps: system characterization; development and evaluation of alternatives; and selection and implementation of the controls. The permittees must also establish a public participation process that actively involves the affected public throughout the plan development.

This report has been prepared to fulfill the requirement for the System Characterization Report as outlined in the individual NJPDES Permit No. NJ0108782 for the City of Elizabeth. The work has been performed according to the Sewer System Characterization Work Plan: Quality Assurance Project Plan (System Characterization QAPP), which was submitted to the NJDEP in December 2015 per the permit conditions and approved upon revisions in May 2016. In future steps of this LTCP process under the current permit cycle, the CSO permittees must prepare and submit a Development and Evaluation of Alternatives Report by July 1, 2019 and a Selection and Implementation of Alternatives Report by June 1, 2020.

The characterization of the City's combined sewer system presented in this report centers on generating, calibrating, and validating a detailed computer model of the collection system to serve as a key tool in assessing the existing system's response to wet weather events. This has been accomplished through comprehensive sewer system records review, mapping, field investigations, and condition assessments; hydrologic and hydraulic monitoring; sewer flow sampling and analytical testing for pathogens; collection system modeling; receiving waters pathogen water quality monitoring; and the consideration of sensitive areas as defined in the EPA National CSO Control Policy. With the validated collection system model and the selection of the typical hydrologic period, the existing CSS performance relative to volume, frequency, and duration of overflows on a system-wide, annual average basis has been simulated. The collection system model will also be used in evaluating CSO control alternatives and selecting LTCP projects in the subsequent steps of the plan development.

Sewer System Description

In the CSO long term control planning process, a full understanding of the combined sewer system is critical to accurately modeling the collection system and characterizing its response to precipitation events. As such, a thorough record review and updated sewer system description,

inventory, and assessment has been compiled. Information from prior reports and record documents was studied and field verified as appropriate. Field work was performed to collect pipe location, connectivity and invert data and to inspect CSO diversion and control structures. This effort also included expanding and upgrading the geographic information system (GIS) for the City sewer system mapping, inventory database, and records management.

The City's wastewater and stormwater collection and conveyance system consists of a complex network of intercepting sewers, sewer mains, manholes, catch basins, pump stations, overflow control facilities, outfalls, and drainage channels. Much of the City has combined sewers that collect and convey sanitary and stormwater flows in the same conduit, but in certain areas, sanitary flows are conveyed in a separate (sanitary) sewer system connected to interceptors and stormwater runoff is conveyed by separate storm sewers and drainage channels. The combined sewer system coverage represents approximately 52.3% of the total 12.3 square miles of land area within the City. However, in terms of sewer lengths, approximately 78% of the total 213 miles of pipe (including sewer mains, outfalls, interceptors, and force mains, but not building sewers and laterals) is comprised of combined sewers, while 18% is classified as separate storm sewers and 4% is classified as separate sanitary sewer.

In general, the major facilities of Elizabeth sewer system include:

- Approximately 160 miles of combined gravity sewer mains and trunks, with an estimated 6,400 manholes and 3,300 inlets and catch basins associated with these lines.
- Approximately 9.5 miles of separate sanitary sewers, with about 310 manholes associated with these lines.
- Approximately 38 miles of separate storm sewers, with an estimated 700 manholes and 1,700 inlets and catch basins associated with these lines.
- Twenty-nine (29) permitted CSO outfall discharge points, 38 regulator and diversion structures, and associated solids/floatables control facilities and tide gate chambers.
- Two (2) intercepting sewer lines, totaling 6.6 miles: 4.3 miles for the Easterly Interceptor and 2.3 miles for the Westerly Interceptor.
- A total of 9 pumping stations: 3 sewage pumping stations and 6 stormwater pumping stations.
- Stormwater drainage ditches and channels that convey stormwater as well as combined sewer overflows in certain locations to receiving waters.

Except for flows from sewers directly connected to the Joint Meeting trunk sewers, wastewater is collected and conveyed by 2 City owned intercepting sewers serving the easterly and westerly portions of the City, respectively. These intercepting sewers flow to the Trenton Avenue Pumping Station (Trenton Avenue PS or TAPS), which is the City's main pumping station located along the west bank of the Elizabeth River in the southern end of the City and only separated by the New Jersey Turnpike from the Joint Meeting WWTP. As such, the Trenton Avenue PS discharges flows to the JMEUC incoming trunk sewer approximately 1,300 feet upstream of the wastewater treatment facilities. The reported 2017 annual average flow from the Trenton Avenue PS to the JMEUC WWTP is 16.3 mgd.

During wet weather conditions, a certain amount of combined sewage is conveyed through the interceptors to the Trenton Avenue PS and pumped to the JMEUC WWTP for treatment. Combined sewage flows over the allowable pumping rate and the collection system conveyance and storage capacities are diverted at regulator structures to the permitted CSO outfalls. There are 29 permitted CSO discharge points within the City: 4 CSO outfalls discharge to Newark Bay (2 via the Great Ditch, 1 via the Peripheral Ditch, and 1 directly to the bay); 4 CSO outfalls discharge to the Arthur Kill; and 21 CSO outfalls discharge to the Elizabeth River. Each CSO

outfall is equipped with an overflow control facility to collect solids and floatables that would otherwise be discharged to the receiving waters.

To identify the location and flow volume of inter-municipal sewer connections, the City of Elizabeth corresponded with adjacent municipalities to request record plans and documents related to the sewer networks along the City border. The City also worked through the Joint Meeting to request record sewer information from member municipalities adjoining the City. From a prior investigation into localized street flooding at the intersection of Park Avenue and Glenwood Road, the City was aware of a 42" diameter storm sewer from the Borough of Roselle Park connecting to the City's combined sewer system in Park Avenue along the municipal boundary at Galloping Hill Road. The City has also reviewed its available sewer mapping to investigate other potential inter-municipal connections. Except for the Roselle Park storm sewer on Park Avenue, the other identified locations are small sewers of short lengths, following local topography, and of limited tributary flow.

In a 2017 draft report, consultants for Roselle Park delineated a 120-acre drainage area as being tributary to the 42" storm sewer connection to the City combined sewer system. The 42" Roselle Park storm sewer connects at the upstream end of a large CSO basin and its considerable impact on the City drainage system was noted in the prior study by the City.

The City has been corresponding with the Borough of Roselle Park regarding the hydraulic connection to the combined sewer system and its impacts and responsibilities of complying with the NJPDES CSO permits. Initial meetings were held and flow data and sewer system information has been provided to Roselle Park representatives. As a hydraulically connected community affecting CSO events in Elizabeth, Roselle Park was also invited and is participating as a member of the Supplemental CSO Team, which was formed per the NJPDES CSO permit conditions on the public participation process to solicit input and share information on the LTCP development.

The receiving waters for the Elizabeth CSOs are the Elizabeth River, Arthur Kill, and Newark Bay. The applicable reaches of the Arthur Kill and Newark Bay are both listed under the NJDEP Surface Water Quality Standards (WQS), N.J.A.C. 7:9B, as saline estuary waters designated use class 3 (SE3). Typical usage of SE3 waters includes: (1) maintenance, migration of fish populations, (2) migration of diadromous fish, (3) maintenance of wild life, (4) secondary contact recreation, and (5) any other reasonable uses. The Peripheral Ditch and Great Ditch are manmade conveyance systems constructed to convey stormwater runoff to the Newark Bay. The Peripheral Ditch and the Great Ditch are not listed in the NJDEP Surface WQS and can be characterized as stormwater conveyance facilities to the Newark Bay receiving waters.

The Elizabeth River is divided into 2 reaches for WQS classification based on salinity content. The lower reach, from the Bridge Street bridge to the mouth, is classified as SE3 and 8 CSO outfalls discharge to this section. The upper reach, from the source to the Bridge Street bridge, is classified as freshwaters category 2, non-trout supporting (FW2-NT) and 13 outfalls discharge to this section. The NJDEP surface water bacterial quality criteria (maximum concentrations) for SE3 and FW2 waters are:

- SE3 waters: Fecal coliform indicator criteria: Geometric Mean: 1,500 colony forming units (cfu)/100mL
- FW2 waters: E. coli indicator criteria: Geometric Mean: 126 cfu/100mL. Single Sample Maximum: 235 cfu/100 mL.

The combined sewer drainage basin, or sewershed, associated with each CSO outfall and its corresponding regulator(s) have been delineated and the various sewer system components and characteristics are described in Section 2. The relationships and connections between the

system components and CSO basins are quite involved, as noted in the system description, mapping, and model schematic. Each regulator is associated with a CSO outfall and either the Easterly or Westerly Interceptor sewer service areas. Some regulators serve as relief diversion structures and discharge to downstream sewersheds tributary to other regulators. For example, the group of interconnected drainage basins tributary to Regulator R005 includes CSO Sub-basins 003A, 003B, 036, and 041. In this case, the dry weather flow pipe from Regulator R003B connects to Regulator R003A, which then in turn connects to the trunk sewer to Regulator R041. Regulators R036A and R036B contribute flow to a separate trunk sewer collecting flow from the Regulator R005 sewershed, which then merges with the trunk sewer from Regulator R041 before connecting to Regulator R005 and subsequently to the Westerly Interceptor. However, there is a wet weather overflow diversion from each of these regulators as well, corresponding to Outfalls 003A, 036A, 041A, and 005A, respectively.

The CSO Sub-basins vary in area from about 3 to 439 acres, with the total CSO basin area being 3,832 acres (excluding 120 acres in Roselle Park tributary to the 42" storm sewer connection). An updated land use analysis was performed using the 2012 NJDEP GIS dataset, which indicates that the overall CSO drainage area is approximately 52.2% high density residential, 8.2% medium density residential, 0.1% low density residential, 17.3% commercial, 11.6% industrial, 3.5% open areas, 3.3% transportation, 1.7% mixed urban, 1.9% other urban, and 0.2% wetlands. The composite impervious cover for the CSO sewershed is about 62%.

The location of significant indirect users (SIUs) relative to the CSO Basins are indicated in the sewer system description and mapping. A total of 17 SIUs are located in Elizabeth, NJ, but only 9 SIUs contribute flow to CSO sewersheds. Given the location, flows, and pretreatment provided, the SIUs appear to have no significant impact on CSOs.

The sewer system description also discusses such items as: population and demographic trends; existing zoning conditions; JMEUC conveyance and treatment facilities; sewer system pipe inventories, interceptors and trunk sewers, and pump stations; facilities assessment; infiltration and inflow analysis; and previous projects for alternatives analysis. The existing information and data on the CSS is fully documented and presented in Section 2.

Hydraulic Monitoring

To generate sufficient data on actual physical conditions to calibrate and validate a collection system hydrologic and hydraulic (H&H) model, the City performed a precipitation and sewer flow monitoring program appropriate for the extent and complexity of the combined sewer system. Per the approved System Characterization QAPP, 40 continuous flow meters, 3 rain gauges, 2 tide gauges, 14 tide gate contact switches, and 2 groundwater level monitors were installed throughout the system for the monitoring period of August 22, 2015 through December 21, 2015. The 40 flow meter locations were distributed as follows: 14 meters on incoming combined sewers upstream of overflow control structures; 10 meters on overflow outfall lines; 6 meters along the Easterly Interceptor; 6 meters along the Westerly Interceptor; and 4 meters on storm sewer lines.

The monitoring data collection and processing activities strictly adhered to the quality assurance procedures identified in the QAPP. The flow meters recorded the flow depth, velocity, and flow data in 5-minute intervals throughout the 4-month monitoring period. The installed rain gauge network provided adequate precipitation monitoring coverage to capture and characterize intense and spatially variable storm events across the overall sewershed. During the monitoring period, a total of 10 precipitation events occurred, varying in duration from 2.8 to 46 hours and in peak intensity from 0.07 to 0.76 inches per hour (in/hr). Various periods of dry weather conditions, defined as a minimum of 3 days of no precipitation following a rainfall exceeding

0.25 inches, or two days of no precipitation following a rainfall 0.25 inches or less, were captured within the monitoring period.

One tide gauge was installed at the Elizabeth Municipal Marina on the Arthur Kill and the other was located on the Elizabeth River at Bridge Street. Readings at the marina were taken as being representative of tides for Newark Bay as well. The observed tidal data for the monitoring period was found to be consistent with National Oceanic and Atmospheric Administration (NOAA) data for the Sandy Hook, NJ station.

The 14 tide gate limit switches were strategically located to assist with the determination of CSO volumes with high tide tailwater conditions using scattergraph techniques. The on/off state of the limit switches monitored the open/closed status of the tide gate position and the time and duration of the limit switch on status were used in CSO quantification at certain locations where backwater conditions were experienced prior to an overflow event.

The 2 groundwater monitors were installed in manholes along Front Street, near the Arthur Kill waterfront, to identify the potential for groundwater infiltration in this low-lying area which has older vitrified clay pipe sewers that may be susceptible to infiltration from leaking manhole and pipe defects. However, the gauges did not record any measurable groundwater levels during the monitoring period.

Wastewater Quality Monitoring

Wastewater quality monitoring data was collected following the approved System Characterization Work Plan Quality Assurance Project Plan to obtain information on dry weather and wet weather indicator bacteria concentrations for CSO pollutant characterization. The data collected will be used in conjunction with the Baseline Compliance Monitoring Program and the pathogen water quality model of receiving waters being developed by the NJ CSO Group.

Seven (7) sampling site locations were selected to obtain a representative understanding of the CSO discharge characteristics across the City. Three (3) discrete sampling events were conducted, coinciding with significant wet weather events meeting the criteria of 0.5 inches or more precipitation occurring within a 24-hour period. Each event was preceded by a period of dry weather, consistent with the definition used for sewer flow monitoring and modeling.

A round of dry weather sampling was conducted the day before each sampled wet weather event. Sampling crews mobilized in advance of a rainfall event and collected wet weather samples as closely as possible to the following time intervals during the event: 0.5 hour, 1 hour, 2 hours, 4 hours, and 8 hours. The wet weather sampling ended upon the collection of an 8-hour sample. All samples collected were analyzed for fecal coliform and enterococcus. Samples from 2 monitoring stations were also tested for *Escherichia coli* (*E. coli*) for characterizing outfall discharges to a freshwater receiving body.

The sewer flow wet weather sampling occurred on November 29, 2016, April 25, 2017, and May 5, 2017, with corresponding daily total precipitation depths of 2.02, 0.87, and 3.05 inches, respectively. The microbiological assays were conducted by Eurofins QC, Inc., a New Jersey certified analytical testing laboratory, at either the Southampton, PA or East Rutherford, NJ laboratory location. Details on the sampling and analytical methods and summaries of the dry weather and wet weather analytical results are given in Section 4.

The results for the wastewater dry weather pathogen concentrations range from 1.40×10^6 to 5.0×10^6 colony forming units (cfu)/100mL for *E. coli*, 1.1×10^6 to 32.0×10^6 cfu/100mL for fecal coliform, and 0.54×10^6 to 5.5×10^6 cfu/100mL for enterococci. Geometric means are typically used for reporting bacteria concentrations to account for the naturally large fluctuations in

microorganism population measurements. The geometric means for the dry weather *E. coli*, fecal coliform, and enterococci concentrations are 2.64×10^6 , 3.82×10^6 , and 0.89×10^6 cfu/100mL, respectively. These values are typical for raw wastewater flows and are consistent with the results from previous monitoring studies.

For the wet weather sewer sampling results, the reported pathogen concentrations from all events, sampling sites, and collection times range from 0.07×10^6 to 11.0×10^6 cfu/100mL for *E. coli*, 0.04×10^6 to 108.0×10^6 cfu/100mL for fecal coliform, and 0.02×10^6 to 6.2×10^6 cfu/100mL for enterococci. The geometric means for the same dataset are 0.50×10^6 , 0.87×10^6 , and 0.36×10^6 cfu/100mL *E. coli*, fecal coliform, and enterococci, respectively. The overall values and ranges for the overflow concentrations are again consistent with typically reported data and prior baseline monitoring data.

For each parameter, the wet weather mean concentration is lower than the mean for the dry weather data, which is indicative of dilution over the course of the wet weather events. While the measured wet weather pathogen concentrations vary by sampling event and location, there appears to be a general decrease in the indicator bacteria concentrations after the 1-hour sample collection times for most events and sites, indicating a concentration decrease after an initial CSO activation and “first flush” period as a higher wet weather flow rate is sustained. There also appears to be a trend to slightly higher concentrations from the 4-hour samples to the 8-hour samples. This may be indicative of decreasing wet weather flow rate as the storm and overflow event ends.

Collection System Modeling

Using the detailed delineation of the existing collection system pipe network conditions and the precipitation and sewer flow monitoring data, a collection system H&H model was developed for the City combined sewer system. A H&H computer model is a mathematical representation of the physical collection system developed to simulate the performance of that physical system. Through appropriate model construction, calibration, and validation, the model is to accurately reflect the combined sewer system’s response to precipitation events, so that the location, frequency, volume, and duration of overflows can be characterized. By predicting the potential real system performance for different modifications and configurations, the model also is to provide a basis for making decisions on long term CSO controls.

The collection system model was developed following the procedures outlined in the System Characterization QAPP and it was compiled using the Innovyze InfoWorks® ICM computer program. InfoWorks® ICM is a widely used software package capable of modeling overland rainfall and runoff responses and accurately calculating hydraulic pipe flows through collection system conveyance links. The software allows an extensive portion of the physical system to be represented, along with the complex network of interconnections and flow conditions occurring within it.

The existing conditions model incorporates all sewers 24” and larger in diameter, and a substantial number of smaller sewers. All interceptor, trunk, overflow control structures, and outfall pipes have been included in the model, along with various sewage and stormwater pumping facilities. This broad model geometry facilitates simulating and routing of dry weather and wet weather flow components throughout the combined sewer collection system.

A dry weather flow (DWF) analysis was conducted on the data from the current collection system monitoring period for each meter with such flows. Dry weather weekday and weekend flows were segregated from the datasets and diurnal peak factors were calculated. The metersheds were analyzed for population estimates and correlated to the sanitary flow

component in the recorded data for that meter. The groundwater infiltration component in the meter data was also translated to unit factors on a metershed basis. The DWF characteristics from the metersheds were then assigned to the broader sewersheds according to the location and physical characteristics of the sewersheds.

Similarly, a wet weather flow (WWF) analysis was performed on the tributary area to each meter, whereby runoff generation characteristics, such as impervious area, initial abstraction, and runoff coefficients, were calculated. These parameters were entered in the modeling program and peak WWF were generated. Adjustments in the WWF generation coefficients were then made as part of the calibration process.

The 10 rainfall events captured during the current monitoring period were classified based on duration and intensity into 4 categories and 4 events were selected for model calibration and 2 events were selected for model validation to cover a range of wet weather conditions. For the selected rainfall events, the simulated model results were compared with the measured data against criteria for peak flow rate, volume, timing of peak, and hydrograph shape. Goodness-of-fit plots noting the overall total volume and peak flows values calculated from the calibrated and validated collection system model against the values from the actual meter data for the 10 storm events are provided in Section 5. The overall model results match the metered data closely, with the majority of the goodness-of-fit values falling on the 45-degree line, indicating an excellent correlation between the simulated and measured flows. Where the simulated values differ from the measured values, the goodness-of-fit points are predominantly above the direct correlation line, signifying that the model is conservatively overestimating the indicated property.

Receiving Water Quality Monitoring and Modeling

As part of the NJ CSO Group collaboration, a field sampling and analytical testing program for existing ambient pathogen water quality conditions in the participating CSO permittees receiving waters has been implemented. The NJ CSO Group Compliance Monitoring Program Report (CMP Report), dated June 2018, has been submitted to the NJDEP by PVSC, as the lead organization of the NJ CSO Group. The CMP Report provides a full narrative of the implemented Baseline Compliance Monitoring Program (BCMP), including the program description; the field sampling and the field and laboratory analytical methods used; the data quality objectives; an evaluation of data completeness, precision, and representativeness; and presentations and discussion of the program results. The intent of the program is to generate sufficient data to establish existing ambient water quality conditions for pathogens in the CSO receiving waters and to update, calibrate and validate a pathogen water quality model of the receiving waterbodies.

The BCMP involved baseline, source, and wet weather event sampling of waterbodies throughout the region, with 11 sampling locations situated in or near the City of Elizabeth, including sampling stations maintained by the New Jersey Harbor Discharges Group (NJHDG). Baseline sampling was performed twice a month in May and June; weekly in July, August, and September; and monthly from October through April. Source sampling occurred at the same time as baseline sampling, but targeted major influent streams within the study area to establish non-CSO loadings. Event sampling was timed to coincide with rainfall to capture 3 discrete wet-weather events and was limited to select sampling locations.

The CMP Report organizes the baseline, source, and event sampling data by waterbody grouping, station number, and specific waterbody. A total of 23 baseline and source events were completed from April 2016 through March 2017, while the wet weather event sampling was completed across 4 sampling dates in June 2016, January 2017, and April 2017. All samples collected were analyzed for fecal coliform and enterococcus and samples from

freshwater locations were also analyzed for E. coli. During field sampling, field measurements were also made for: temperature, salinity, dissolved oxygen, light penetration (secchi depth), and turbidity. Depending on the sampling location, samples were collected at either 1 or 2 depths. For event sampling, locations were typically sampled twice per day for 3 days.

The Compliance Monitoring Program Report presents the ambient water quality data collected under the program as 6-panel time series plots, which are reproduced in Section 6 for the sampling locations in or near the City of Elizabeth. The following findings were noted from the BCMP data:

- The baseline ambient monitoring data collected meets the goals of the corresponding Quality Assurance Project Plan and the data is sufficient for calibrating the pathogen water quality model that is being developed.
- While the program was not intended to assess current attainment of pathogen water quality standards because of insufficient data points per month, certain general observations on the likelihood of current attainment conditions can be made:
 - Newark Bay, Arthur Kill, and Kill Van Kull may meet existing pathogen WQS for SE3 waters. The Hudson River also appears to meet existing water quality criteria, while the Raritan Bay is subject to more stringent shellfishing water quality standards.
 - Smaller riverine waterbodies, like the Elizabeth River, Saddle River, Second River, and Rahway River, appear unlikely to meet attainment.
 - The lower regions of the Passaic and Hackensack Rivers also appear likely to violate existing water quality criteria, but attainment appears to improve closer to Newark Bay.
- Source sampling of tributary streams shows that many rivers without CSOs have high bacteria loads, indicating the high contributing pollutant loads from sources other than CSOs.
- Bacteria values in the Elizabeth River waters entering the City are very high, do not meet WQS, and are not CSO impacted.
- Bacteria values in the Elizabeth River upstream and downstream of CSO outfalls are similar. As the number of CSO outfalls tributary to the river increase further downstream, the ambient in-stream monitoring data does not demonstrate a direct relationship between baseline pathogen concentrations and the presence of tributary CSO outfalls.
- Wet weather event data fall at the upper end of the observed ambient water quality results. However, it should be recognized that combined sewer overflows are only one of many wet weather pollution sources that may be influencing the higher in-stream pathogen concentrations coincident with the wet weather event sampling data and the contribution of the other pollution sources must be considered.

Furthermore, the NJ CSO Group is developing a Pathogen Water Quality Model (PWQM) for consideration in the CSO LTCP alternatives selection and Compliance Monitoring Program. The PWQM is being created to supplement ambient in-stream pathogen monitoring under the baseline CMP and facilitate the evaluation of CSO control approaches and alternatives. Water quality data collected under the baseline CMP and collection system characterization work is being used to calibrate and validate the PWQM. It is a computational model of the receiving waters that may be used to simulate bacteria concentrations in the waters of the New York-New Jersey Harbor complex under existing conditions and to assess the attainment of applicable water quality standards under potential future conditions. The PWQM will function as a validated tool that reasonably replicates the observed timing, duration, and magnitude of ambient pathogen data in the study area and that is capable of simulating pathogen water quality

conditions for varying CSO strategies to assist in assessing the CSO impacts on ambient pathogen water quality.

Consideration of Sensitive Areas

Consistent with the requirements of the National CSO Control Policy, the NJPDES CSO Permits stipulates that the highest priority must be given to controlling overflows to sensitive areas. The permits define sensitive areas as designated Outstanding National Resource Waters; National Marine Sanctuaries; waters with threatened or endangered species and their habitat; waters used for primary contact recreation (including but not limited to bathing beaches); public drinking water intakes or their designated protection areas; and shellfish beds. If a CSO outfall discharges to a sensitive area, the CSO outfall is to be eliminated or relocated wherever physically possible and economically achievable, and where elimination or relocation is not feasible, treatment of the overflow deemed necessary to meet water quality standards must be provided. The implementation schedule for the LTCP must also place the highest priority to controlling CSOs to sensitive areas.

A thorough assessment of the potential need for a higher prioritization of any specific CSO discharge location in the City of Elizabeth due to the presence of sensitive areas has been conducted. This work includes a detailed investigation of the subject waterbodies performed by the NJ CSO Group on behalf of the participating permittees, as described in the Identification of Sensitive Areas Report, dated June 2018, submitted by PVSC to the NJDEP. Additional consideration of the City of Elizabeth setting, incorporating discussions and input from the Supplemental CSO Team, has been made and is described in Section 7 of this report. Based on these examinations, the City has determined that no sensitive areas exist within its receiving waters and community and no elevated or accelerated CSO controls for sensitive areas are required.

Characterization of System Performance

The EPA National CSO Control Policy indicates that CSO control alternatives be assessed on a “system-wide, annual average basis”. This can be accomplished by selecting a typical hydrologic year and using the precipitation records for the period in a continuous simulation modeling application of the hydraulically connected system. The selection of a typical hydrologic record serves to provide a representative and unbiased prediction of average design rainfall conditions that incorporates the variability observed in the historical records. In conjunction with the NJ CSO Group, local historical rainfall data and storm patterns were analyzed and calendar year 2004 was selected as the typical year hydrologic dataset for the LTCP efforts by the NJ CSO Group permittees. With the submission of the Typical Hydrologic Year Report by PVSC on behalf of the NJ CSO Group, the NJDEP responded in May 2018 that the submitted report addressed all its questions and comments to its satisfaction.

The typical year H&H model simulation for the existing collection system conditions results in an estimated total annual overflow volume from all CSO outfalls of 1,065 million gallons (Mgal) per year. The results for the typical year number of overflow events, overflow volume, and duration, and the peak flow occurrence by outfall location are shown in the table below. The durations noted are the total cumulative time of CSO discharge through the year for the indicated outfall location. The system-wide event counts, durations, and peak flows are the maximum values observed across all outfalls for the year. Section 8 and Appendix J provide additional details on the typical year existing conditions simulation results.

Typical Year Existing Conditions Annual Total CSO Characterization by Outfall

Outfall No.	Outfall Name	Annual Total		Maximum	
		No. Overflow Events	Overflow Volume (Mgal)	Duration (hours)	Peak Flow (mgd)
001A	Airport South Area	35	75.78	246.26	75.09

1 Introduction

This System Characterization Report has been prepared on behalf of the City of Elizabeth (City) to meet certain conditions of the New Jersey Pollutant Discharge Elimination System (NJPDES) individual permit actions issued by the New Jersey Department of Environmental Protection (NJDEP) for Combined Sewer Overflow (CSO) control, with an effective date of July 1, 2015 (referred herein as the NJPDES CSO permits). As permittees of a hydraulically connected system, the City and the Joint Meeting of Essex and Union Counties (JMEUC or Joint Meeting) are cooperating and collaborating on the development of a Long Term Control Plan (LTCP) for CSO control per the permit conditions.

While the City and JMEUC are jointly working towards a single, coordinated LTCP to address the permit requirements, a separate System Characterization Report has been prepared by each permittee for their respective facilities, with the elements of each report having been coordinated and reviewed between the permittees. The City and JMEUC are communicating regularly, sharing information, and exchanging hydraulic models for appropriate characterization, monitoring, and integrated modeling of the hydraulically connected system. Furthermore, each permittee is documenting this coordination and collaboration of materials by certifying each System Characterization Report for the submission to the NJDEP.

1.1 Background

The City of Elizabeth provides wastewater and stormwater collection and conveyance services to about 128,600 people within its municipal boundaries, which encompasses approximately 12.3 square miles in Union County, NJ. This collection and conveyance system consists of an extensive network of sewers, manholes, catch basins, pump stations, overflow control facilities, and drainage conduits, totaling over 210 miles of pipe. The City of Elizabeth does not own or operate any wastewater treatment plant facilities; wastewater flows are conveyed to the JMEUC wastewater treatment plant (WWTP) in Elizabeth, NJ. The City owned sewer system assets are operated and maintained through a multi-year service contract with E'Town Services LLC, a subsidiary of American Water.

Much of the City is served by a combined sewer system (CSS) that collects and conveys sanitary and stormwater flows in the same conduit. The combined sewers are prevalent throughout the northern, western, and southern sections of the City, coinciding with its historical residential, industrial, and commercial development. The existing combined system includes regulators and diversion structures, solids and floatables control facilities, interceptor connections, and outfalls at various locations. In other areas of the City, sanitary flows are conveyed in a separate (sanitary) sewer system connected to interceptors, with stormwater runoff conveyed by a separate storm sewer system.

All dry weather sewage from the City owned sewer system is conveyed to and treated at the JMEUC WWTP. JMEUC is a regional wastewater conveyance and treatment public entity formed by joint meeting of its member municipalities and the WWTP serves more than 600,000 residents in several towns of Essex and Union counties, covering a 65-square mile service area. The treatment plant is designed for an average daily flow of 85 million gallons per day (mgd), but can process additional quantities of flow during wet weather events. The City of Elizabeth is a customer to JMEUC, not a member municipality, and is currently contractual limited to an 18 mgd maximum average daily flow and a 36 mgd maximum instantaneous peak discharge from its main wastewater pumping station to the JMEUC treatment works.

1.2 Regulatory Context and Requirements

In 2015, the New Jersey Department of Environmental Protection revoked prior authorizations related to combined sewer overflows under NJPDES Master General Permit No. NJ0105023 and issued individual permits to authorize discharges from CSOs. Discharges from the City of Elizabeth's 29 designated CSO locations are authorized and regulated by NJPDES Permit No. NJ0108782. While the Joint Meeting does not own or operate CSO discharge points, the downstream portion of the JMEUC trunk sewer system receives and conveys combined sewage from the City and the systems are hydraulically connected. As such, the NJDEP revoked and reissued the JMEUC individual Category "A" Permit No. NJ0024741 to incorporate the prior General Permit Authorization No. NJG0108740 and updated CSO permit requirements as part of the recent CSO permit actions.

In the current NJPDES CSO Permit, the NJDEP has mandated that the permittees prepare a CSO Long Term Control Plan and the NJDEP has incorporated permit conditions that closely reflect the requirements of the National CSO Control Policy established by United States Environmental Protection Agency (EPA). A CSO LTCP involves a comprehensive study of the hydraulically connected sewer system and the evaluation of alternatives for reducing CSO impacts to receiving waters. It investigates the hydrologic and hydraulic relationships between precipitation, conveyance, treatment capacity, and overflows and includes a feasibility study to evaluate the scope, costs, and performance of possible control alternatives for reducing the frequency and volume of CSO discharges.

The National CSO Control Policy and the NJPDES CSO Permits describe 9 elements for the CSO Long Term Control Plan:

1. Characterization, monitoring, and modeling of the combined sewer systems to provide a thorough understanding of the hydraulically connected system, its response to various precipitation events, the characteristics of the overflows, and the water quality impacts that result from the CSOs;
2. A public participation process that actively involves the affected public in the decision-making to select long term CSO controls;
3. Consideration of sensitive areas in identifying the highest priority for controlling overflows;
4. Evaluation of alternatives that considers a reasonable range of CSO control options that provide a level of control presumed (per the criteria given in the Policy and Permit) or demonstrated to meet the water quality-based requirements of the Clean Water Act (CWA);
5. Cost/performance considerations to demonstrate the relationships among a comprehensive set of reasonable control alternatives;
6. Operational plan that incorporates revisions to the operation and maintenance program necessary after approval of the LTCP to incorporate its associated CSO controls;
7. Maximizing treatment at the existing publicly owned treatment works (POTW) treatment plant during and after each precipitation event so that such flows receive treatment to the greatest extent practicable utilizing existing tankage for storage, while still meeting permit limits;
8. An implementation schedule addressing the construction and financing of proposed CSO controls; and
9. A post-construction compliance monitoring program adequate to verify compliance with water quality-based CWA requirements and ascertain the effectiveness of implemented CSO controls.

The NJPDES CSO Permit divides the LTCP submittal requirements into 3 sequential steps, with documents submitted under each step per the specified schedule:

- Step 1 incorporates the characterization, monitoring, and modeling element and components of the public participation process, consideration of sensitive areas, and compliance monitoring program. It is further divided into the following submittal requirements and schedule:
 - Permittees were required to submit a System Characterization Work Plan within 6 months from the effective date of the permit (EDP), which corresponded to a due date of January 1, 2016. As noted below, the City of Elizabeth submitted this document on time and the approved work plan served as the basis for the subsequent characterization, monitoring, and modeling efforts described in this report.
 - Permittees are required to submit a System Characterization Report within 36 months of the EDP, which equates to a due date of July 1, 2018. This report is being submitted in fulfillment of this permit condition.
 - Permittees are also required to submit a Public Participation Process Report and a Consideration of Sensitive Areas Information document within 36 months from the EDP (i.e., July 1, 2018).
 - Although listed separately from the steps in the permit under the LTCP Submittal Requirements, permittees were also required to submit a baseline Compliance Monitoring Program (CMP) Work Plan by January 1, 2016 and are then required to submit a baseline CMP Report and data within 36 months of the EDP, or again July 1, 2018. The City of Elizabeth is collaborating as part of the NJ CSO Group, a coalition of New Jersey CSO permittees, to satisfy these permit conditions through a regional ambient water quality sampling and testing program and pathogen water quality modeling, as further noted in this report.
- Under Step 2, permittees are required to submit a Development and Evaluation of Alternatives Report within 48 months from the EDP, or a due date of July 1, 2019. This step involves evaluating a broad range of control alternatives to meet CWA requirements and water quality standards (WQS) using either the “Presumption” Approach or “Demonstration” Approach and the corresponding conditions prescribed in the permit. Maximizing treatment at the existing POTW treatment plant and cost and performance considerations also need to be addressed in Step 2.
- Under Step 3, permittees are required to submit a Selection and Implementation of Alternatives Report that incorporates the final plan selection and implementation schedule for the construction and financing of proposed CSO controls. A proposed operational plan revision schedule and a post-construction compliance monitoring program also should be addressed. This submittal is due within 59 months from the EDP, which corresponds to a due date of June 1, 2020.

This report has been prepared to fulfill the requirement for the System Characterization Report as outlined in the individual CSO NJPDES Permit No. NJ0108782 for the City of Elizabeth. The work has been performed according to the Sewer System Characterization Work Plan: Quality Assurance Project Plan (QAPP), which was submitted to the NJDEP in December 2015 per the permit conditions and approved upon revisions in May 2016.

The NJPDES CSO Permit further stipulate that each permittee must work cooperatively with other permittees and municipalities in a hydraulically connected system such that the LTCP is developed consistently based on the same data, characterization, analysis methods, and results. As noted above, the City and JMEUC are actively collaborating on the various elements

of the LTCP and each System Characterization Report considers the same conditions and data where appropriate to ensure that the information given is consistent.

The City and JMEUC are also involved as members of the regional assembly of NJPDES CSO permittees referred to as the NJ CSO Group. Members of this group consist of municipalities, sewerage authorities, and other entities that have been issued a NJPDES CSO permit and have agreed to work jointly in addressing common and overlapping areas for permit compliance. On behalf of the member permittees, the NJ CSO Group, with the Passaic Valley Sewerage Commission (PVSC) serving as the managing member, is providing shared services for these common elements of the CSO permits to avoid costly and inefficient duplication of efforts. These shared services encompass certain water quality monitoring and modeling work, such as ambient in-stream sampling and testing, baseline compliance monitoring reporting, and pathogen receiving water quality modeling; production of CSO outfall identification signs; setup and operation of a CSO notification system website; and coordination with regulatory agencies on common issues for permit compliance. This regional partnership also assists in sharing information and gathering feedback on techniques for public involvement and CSO controls.

1.3 Report Goals and Objectives

A hydrologic and hydraulic collection system model is a mathematical representation of the physical collection system developed with the goal of realistically simulating the performance of that physical system. By ensuring a good model match to the physical system under actual measured conditions, the model can be considered a reliable tool for understanding the system's performance under other conditions to be evaluated, such as with system modifications for a typical hydrologic period. Establishing the model as a reliable tool is critical since the model is the primary tool for assessing current system performance as well as for the planning, evaluation, and design of future system improvements. By developing a high-quality collection system model, the City, in collaboration with JMEUC, will be able to evaluate system improvements that will meet operational and regulatory goals.

This System Characterization Report has been developed to provide a comprehensive characterization of the existing combined sewer system, acquired through detailed records review, monitoring, and modeling. The program objectives addressed herein are:

- Conduct a thorough record review and compile an updated sewer system description, inventory, and assessment;
- Prepare an updated drainage area land use analysis;
- Compile site specific dry and wet weather monitoring data adequate to define the existing sewer system hydraulic response to rainfall, calibrate and validate a hydraulic system model, and estimate pathogen pollutant concentrations in CSO discharges;
- Generate a collections system model for the purposes of evaluating CSO control alternatives and developing the LTCP by updating and enhancing the existing model and calibrating and validating it with the monitoring data;
- Identify any potential sensitive areas where CSOs occur;
- Consolidate and assess the baseline Compliance Monitoring Program data for receiving waters associated with the City of Elizabeth combined sewer overflows; and,
- Compute and present the existing conditions simulation results from the calibrated and validated hydraulic model for the typical year precipitation record.

The contents of this report collectively relate to each of these objectives and provide the information necessary for the Elizabeth portion of the hydraulically connected system to advance the LTCP process to alternatives evaluation.

1.4 System Characterization Information from Prior Reports and Record Documents

The characterization of the City's combined sewer system presented in this report is based in part on information from various previous reports, studies, field investigations, and operational plans commissioned by the City. The references include record drawings and mapping, facilities inventory and assessment analyses, internal manhole and sewer main inspection reports, condition assessments and rehabilitation plans, drainage and land use studies, and operation and maintenance manuals. As part of this characterization effort, the information from the prior documents has been thoroughly reviewed, field verified, revised, and updated as appropriate, and confirmed to be accurate and representative of the existing properly operated and maintained sewer system.

To manage the volume of record materials and provide a supporting platform of the hydraulic computer model development, the City has greatly expanded and upgraded its geographic information system (GIS) for the sewer system mapping and inventory database. This spatially organized database serves as an excellent tool for the system characterization, recording and tracking key asset information and strategic planning for asset management, operations, and maintenance efforts.

Reports from previous permit cycle submissions were consulted to review prior characterization methodologies for monitoring and modeling and the corresponding results for correspondence and consistency with the current program. These reports include:

- Combined Sewer Overflow Characterization Study, Quality Assurance Work Plan, prepared by Hatch Mott MacDonald, dated January 2006;
- Combined Sewer Overflow Characterization Study, Combined Sewer System Modeling Study Work Plan, prepared by Hatch Mott MacDonald, dated June 2006;
- Combined Sewer Overflow Discharge Characterization Study, Baseline Monitoring Report, prepared by Hatch Mott MacDonald, dated December 2006;
- Combined Sewer Overflow Discharge Characterization Study, Supporting Laboratory Data, prepared by Hatch Mott MacDonald, dated December 2006;
- CSO Long Term Control Plan, Cost & Performance Analysis Report, Volume 1, prepared by Hatch Mott MacDonald, dated March 2007; and
- CSO Long Term Control Plan, Cost & Performance Analysis Report, Volume 2 - Technical Guidance Manual, prepared by Hatch Mott MacDonald, dated March 2007.

1.5 Related Permit Submissions and Reports

The following work plans and reports have been submitted separately to the NJDEP per the NJPDES CSO Permit requirements and are referenced in this report:

- System Characterization Work Plan: Quality Assurance Project Plan, prepared by Hatch Mott MacDonald on behalf of the City of Elizabeth, dated December 2015, revised May 2016.
- System Characterization Report, prepared by CDM Smith on behalf of the Joint Meeting of Essex and Union Counties, dated June 2018.
- Baseline Compliance Monitoring Program Quality Assurance Project Plan (QAPP), prepared by the Passaic Valley Sewerage Commission on behalf of participating permittees of the NJ CSO Group, dated December 2015, revised May 2016.

- NJ CSO Group Compliance Monitoring Program Report, prepared by the Passaic Valley Sewerage Commission on behalf of participating permittees of the NJ CSO Group, dated June 2018.
- Pathogen Water Quality Model (PWQM) Quality Assurance Project Plan (QAPP), prepared by the Passaic Valley Sewerage Commission on behalf of participating permittees of the NJ CSO Group, dated May 2016, revised January 2017.
- Identification of Sensitive Areas Report, prepared by the Passaic Valley Sewerage Commission on behalf of participating permittees of the NJ CSO Group, dated June 2018.
- Typical Hydrologic Year Report, prepared by the Passaic Valley Sewerage Commission on behalf of participating permittees of the NJ CSO Group, dated May 2018.
- Public Participation Process Report, prepared by Mott MacDonald on behalf of the City of Elizabeth and Joint Meeting of Essex and Union Counties, dated June 2018.

1.6 Report Organization

This section introduces the overall project background, regulatory requirements, and the purpose and general contents of the report. Section 2 presents a detailed description of the existing Elizabeth sewer system, including characteristics for the CSO outfalls, regulators and diversion structures, land use, sewer system inventory, facilities assessment, and drainage area descriptions. A summary of the recent hydrologic and hydraulic monitoring performed to facilitate the hydraulic computational model development is given in Section 3. Section 4 provides the results of the sewer system flow sampling and analytical testing for pathogen concentrations corresponding to dry and wet weather sampling to assist in characterizing the pathogen loads in CSO discharges.

Section 5 discusses the development of the updated and enhanced hydraulic model, including the analysis for dry and wet weather flow components, extraction parameters, calibration procedures and results, and model validation methods and results. Section 6 contains a summary of the ambient water quality sampling and data collected through the regional collaboration of CSO permittees under the NJ CSO Group baseline CMP. Information on the consideration of sensitive areas for the Elizabeth CSO outfall locations and receiving waters is presented in Section 7. The analyses for the typical year precipitation period selection and the model simulation results for the existing sewer system configuration and the typical year precipitation record are provided in Section 8. As such, Section 8 incorporates the predicted performance of the Elizabeth combined sewer system for the typical year precipitation data, including the frequency, volume, and duration of the predicted overflows.

Several appendices are also provided to supplement and support the information given in the various report sections.

2 Sewer System Description

2.1 Background

The City of Elizabeth (City) is a major urban municipality located in eastern Union County, New Jersey, and is situated along the west banks of the Arthur Kill and Newark Bay. The City is the state's 4th largest municipality by population with approximately 128,000 inhabitants. As shown on the location map of Figure 2-1, the City is bounded by the City of Newark (in Essex County, NJ) to the north, by the Townships of Hillside and Union to the northwest, by the Boroughs of Roselle Park and Roselle to the west, and by the City of Linden to the southwest. Bayonne (in Hudson County, NJ) is located to the east across Newark Bay and the borough of Staten Island (New York) is located across the Arthur Kill to the south.

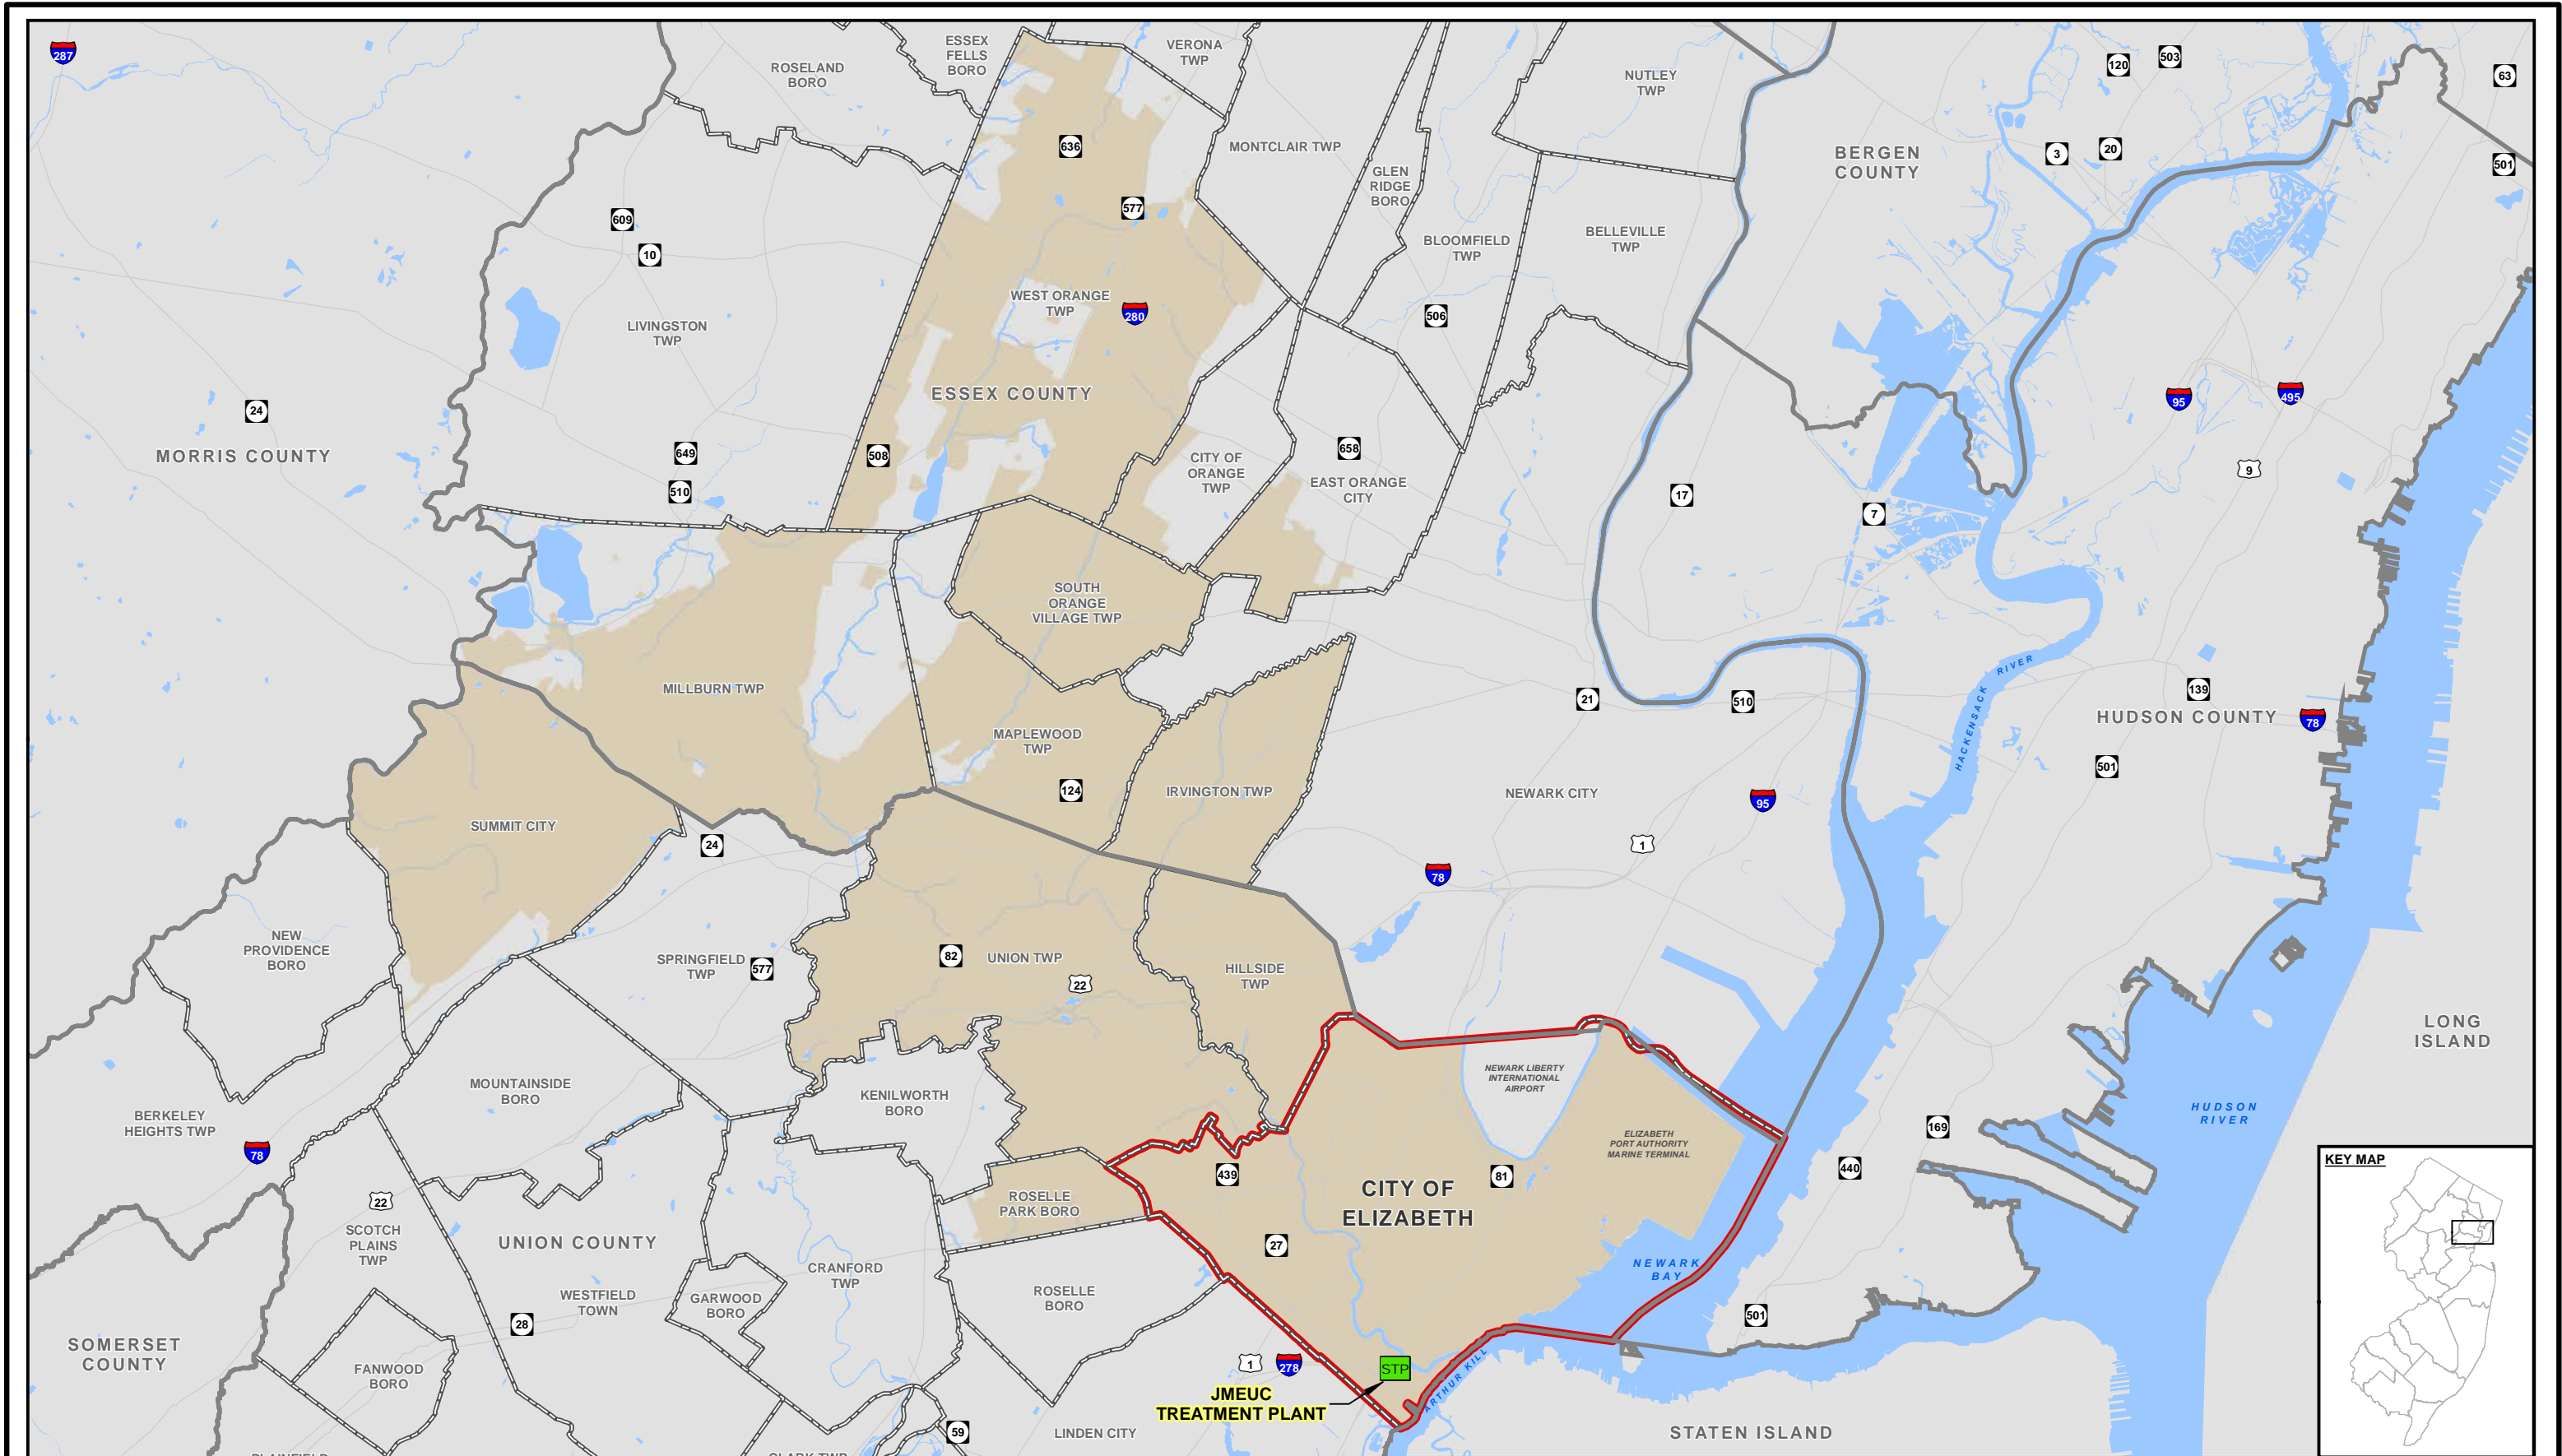

Several significant transportation systems and shipping facilities are located in the City, including the New Jersey Turnpike (Interstate I-95) and associated infrastructure for Exits 13 and 13A, Interstate I-278 and the Goethals Bridge interchange; US Route 1-9; a portion of the Newark Liberty International Airport; Port Elizabeth Marine Terminal; and the Amtrak Northeast Corridor and Conrail Elizabeth Industrial Track rail lines. With this large infrastructure system, the City of Elizabeth is an important residential, commercial, and transportation center in the metropolitan New York area.

The City is the Union County seat and the county courthouse, administration building, sheriff's office, and jail are located within the municipal limits. Union County College, a public community college offering various study programs, also has facilities located within Elizabeth, with a campus that serves over 8,000 students and houses the second largest nursing school in the United States.

The City provides wastewater and stormwater collection and conveyance services to its customers through an extensive network of sewers, manholes, catch basins, pump stations, overflow control facilities, and drainage conduits that comprise the existing sewer system. The City of Elizabeth does not own or operate any wastewater treatment plant facilities; wastewater flows are conveyed to the Joint Meeting of Essex and Union Counties (JMEUC or Joint Meeting) wastewater treatment plant (WWTP) in Elizabeth, NJ.

The Joint Meeting of Essex and Union Counties is a regional wastewater conveyance and treatment public entity formed by joint meeting of its member municipalities. The JMEUC WWTP serves more than 600,000 residents in several communities of Essex and Union Counties within a 65-square mile area. The JMEUC service area is depicted on Figure 2-1. The 11 member municipalities of Joint Meeting are East Orange, Hillside, Irvington, Maplewood, Millburn, Newark, Roselle Park, South Orange, Summit, Union, and West Orange. In addition, Joint Meeting serves the City of Elizabeth as a customer municipality and small portions of Livingston, Orange, Berkeley Heights, Linden and New Providence are served through member or as customer systems.

The City of Elizabeth Department of Public Works is the primary municipal entity responsible for providing wastewater and stormwater collection and conveyance services for the City's residents, businesses, and institutions. The City owns its sewer system assets and has entered into a multi-year service agreement for the operation of the system with E'Town Services LLC, a subsidiary of American Water, an investor-owned water and wastewater utility service company. As noted above, the owner and operator of the publicly owned treatment works receiving the

Elizabeth sewer system flows is the Joint Meeting of Essex and Union Counties, located in Elizabeth, NJ.

Much of the City is served by a combined sewer system (CSS) that collects and conveys sanitary and stormwater flows in the same conduit. In certain areas, sanitary flows are conveyed in a separate (sanitary) sewer system connected to interceptors and stormwater runoff is conveyed by separate storm sewers and drainage channels. Figure 2-2 shows the coverage of the sewer system types across the City.

A combined sewer system is designed to carry sanitary sewage at all times and is also designed to collect and transport stormwater from streets and other sources, thus serving a combined purpose. During dry weather, a combined sewer system conveys the sanitary sewage to the wastewater treatment plant. During wet weather, the combined flow of wastewater and storm runoff may exceed the intercepting capacity of the sewer system and result in a combined sewer overflow (CSO), which is the excess flow from the system that is not conveyed to the domestic treatment works (DTW), but discharges through a pipe or channel to a receiving water.

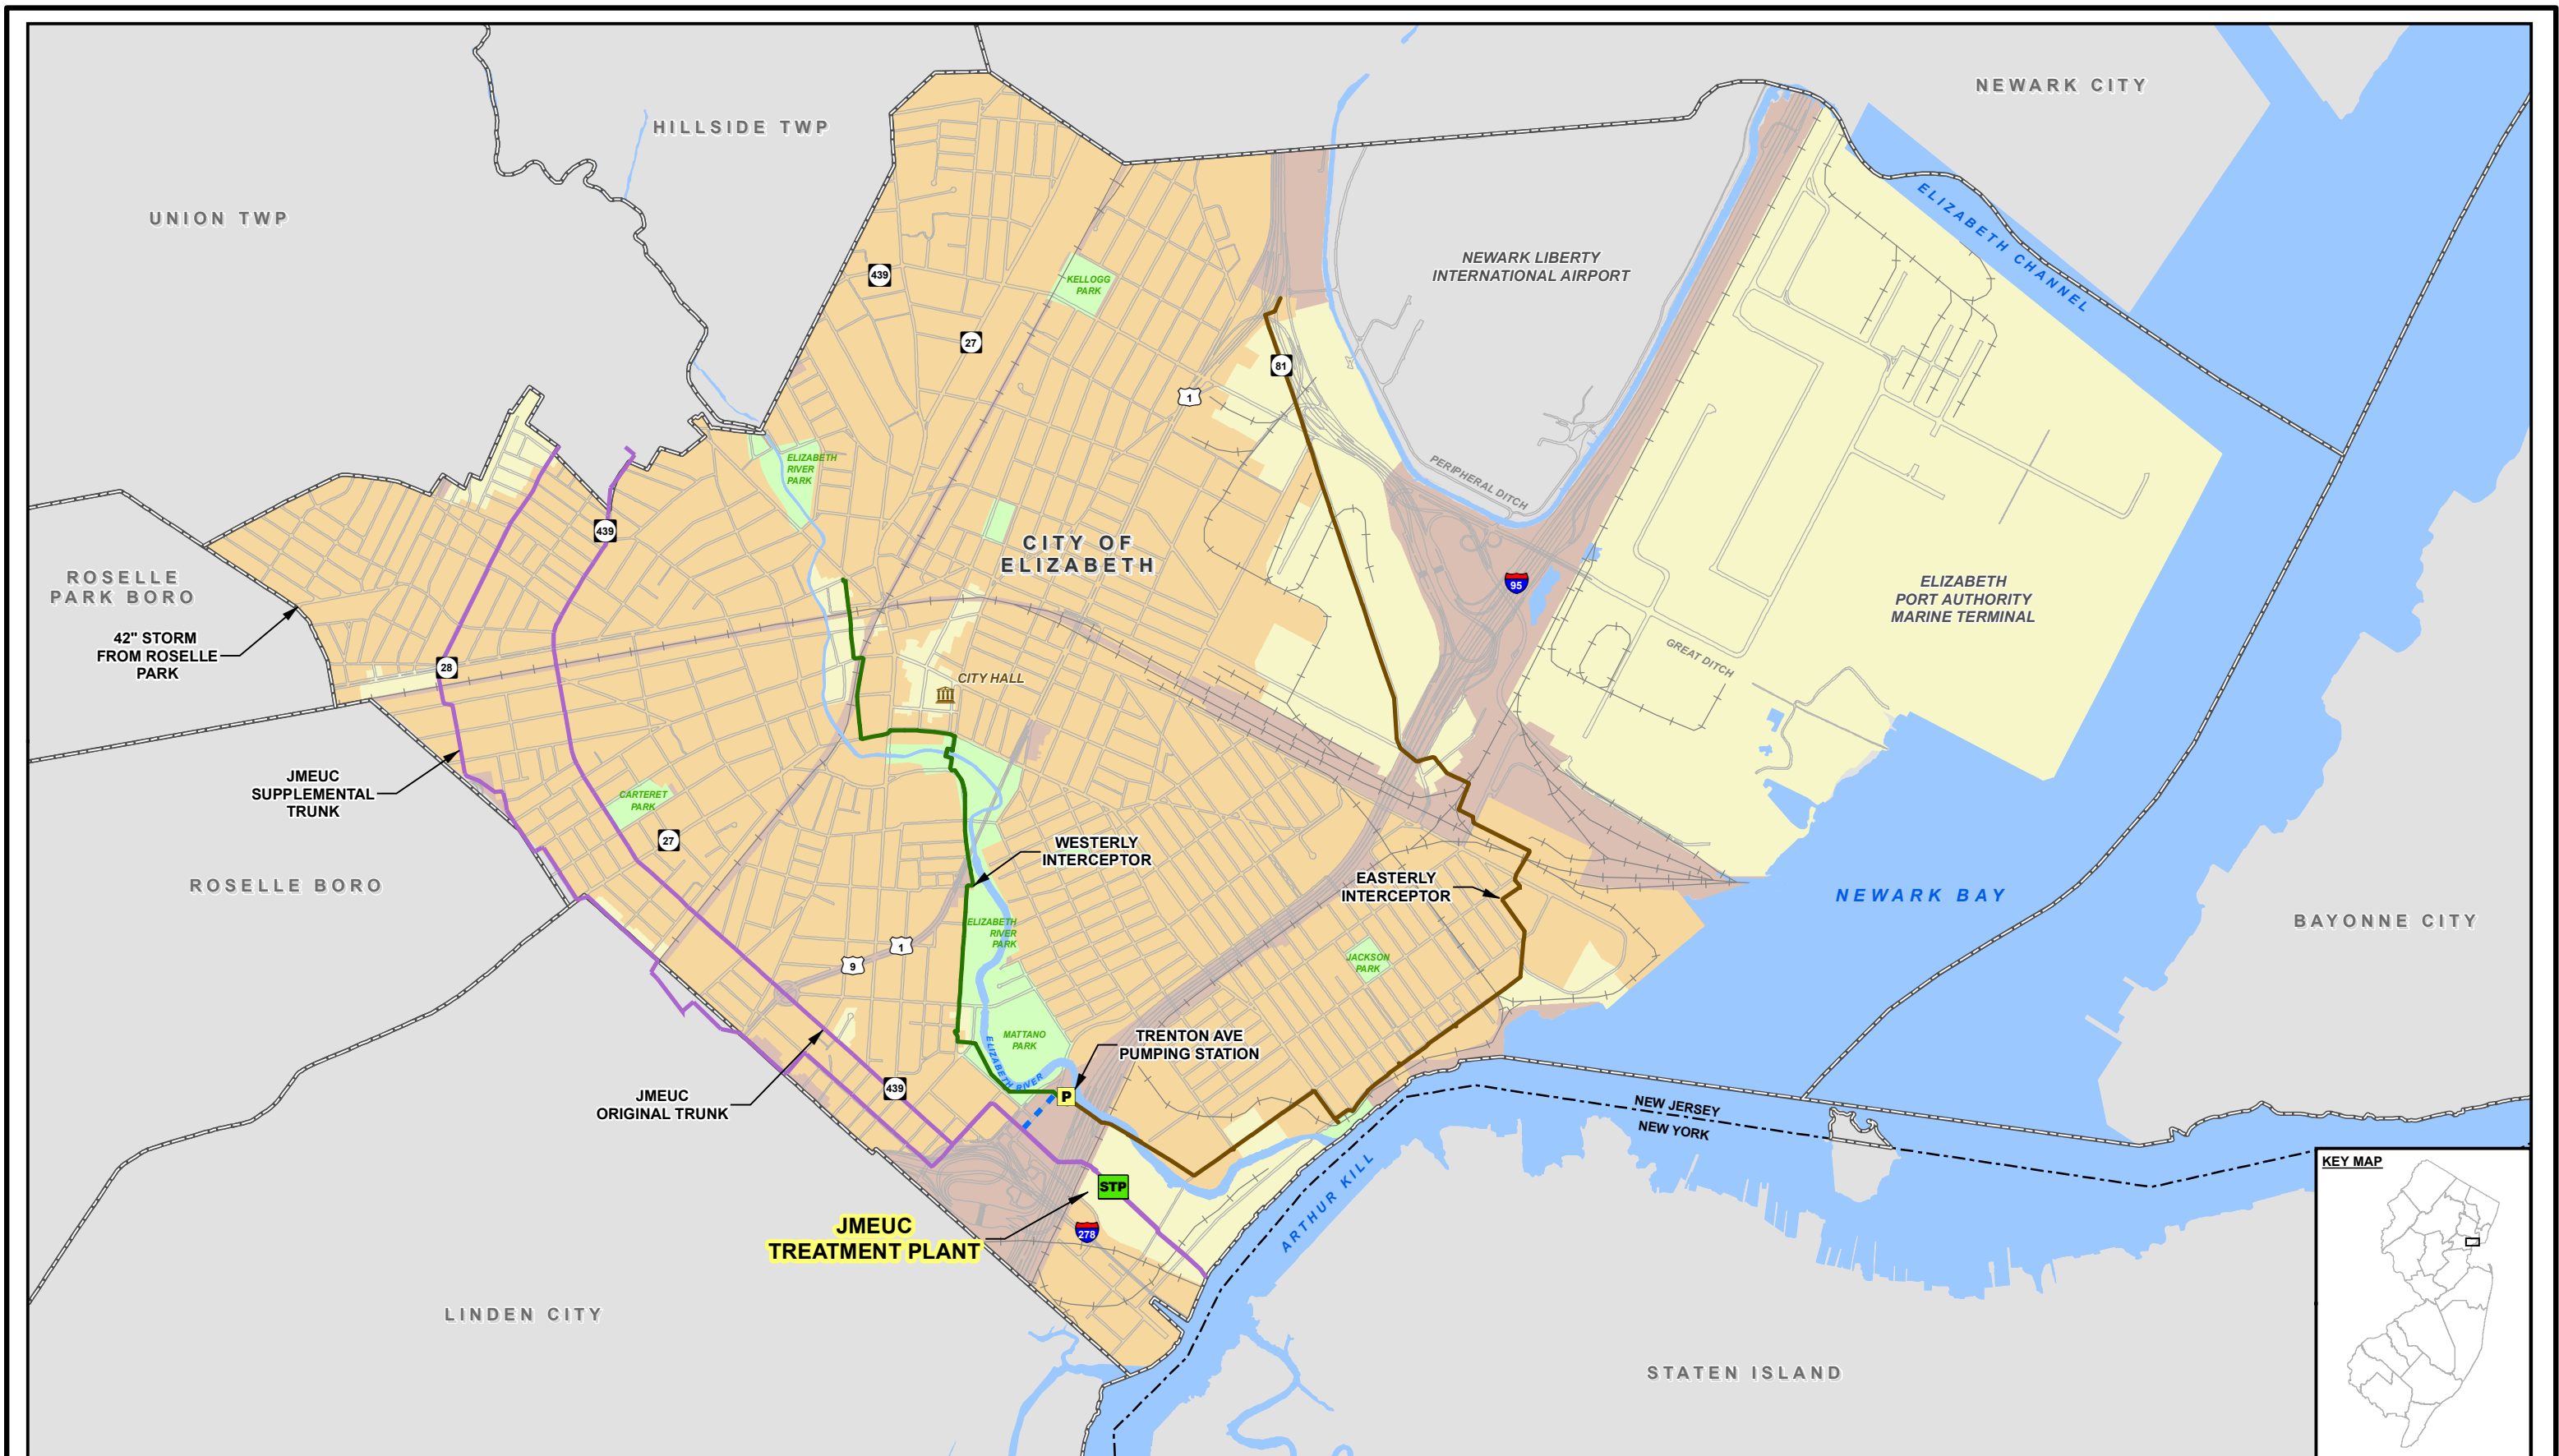

As defined by NJDEP, a separate sewer system is designed to only carry sanitary sewage and not intended to collect and transport stormwater from streets and other sources. The NJDEP regulations further describe separate storm sewers as conveyance (including roads with drainage systems, streets, catch basins, gutters, ditches, man-made channels, or storm drains) designed or used to collect or convey stormwater and which are not part of a combined sewer system or of a publicly owned treatment works.

Of the City's total land area (excluding water bodies) of 12.3 square miles, about 11.2 square miles are situated in the JMEUC sewer service area, with the balance being the Newark Liberty International Airport site, which has a separate sewer system tributary to the Passaic Valley Sewerage Commission (PVSC) service area. As it is maintained by the Port Authority of New York and New Jersey (Port Authority) and not hydraulically connected to the City sewer system, the area within the airport is excluded from further analysis herein.

Of the City area within the JMEUC service area, an estimated 3.45 square miles have separate sewer systems, 6.39 square miles have combined sewer systems, and 1.36 square miles do not generate sanitary sewage flows, consisting of major highway infrastructure corridors. The combined sewer system coverage represents approximately 52.3% of the land area within the City. However, in terms of sewer lengths, there is approximately 166 total miles associated with the combined sewer system, versus 9 miles of separate sanitary sewers and 38 miles of separate storm sewers.

The majority of the separate sewer system area is set in the eastern portion of the City and includes the commercial and industrial redevelopment areas of North Avenue East, Kapkowski Road, and the Port Elizabeth Marine Terminal. There are also small pockets of separate sewer systems along the Elizabeth River and the western border, corresponding to direct connections to the City interceptor and JMEUC trunk sewers.

The combined sewer systems are prevalent throughout the northern, western, and southern sections of the City, coinciding with its historical residential, commercial, and institutional development. The system includes regulators and diversion structures, interceptor connections, and outfalls at various locations. It is further noted that in certain locations, the combined sewers do not have diversions to outfalls for discharge to receiving waters; instead they are directly connected to intercepting sewers. A total area of about 0.93 square miles contribute combined sewage flow directly to City interceptor and JMEUC trunk sewers, without overflow diversion, and is shown on Figure 2-2 as part of the CSS area. A total area of approximately

5.46 square miles is tributary to combined sewer overflow control points and is further delineated as the CSO drainage basins on subsequent maps herein.

Discharges from the City's designated CSO monitored locations are authorized and regulated by New Jersey Pollutant Discharge Elimination System (NJPDES) Permit No. NJ0108782 (referred herein as the CSO Permit). There are 29 permitted CSO discharge points within the City: 4 CSO outfalls discharge to Newark Bay (2 via the Great Ditch, 1 via the Peripheral Ditch, and 1 directly to the bay); 4 CSO outfalls discharge to the Arthur Kill; and 21 CSO outfalls discharge to the Elizabeth River. The permitted CSO outfall discharge points are listed in Table 2-1.

Overall, the catchment areas involve a complex network of intercepting sewers, sewer mains, CSO outfalls, and storm drains and further descriptions are provided later in this section. The locations of the CSO outfall discharge points and major sewer system components are depicted on Figure 2-3, Figure 2-4, and Figure 2-5 for the northwestern, northeastern, and southern sections of the City, respectively. The location of the CSO outfall discharge points and the major facilities associated with the Elizabeth sewer system are also shown on Plate A, which is a large format map exhibit included in Appendix A at the end of this report. The figures and plate also indicate the delineation of the combined sewer drainage basins, or sewersheds, tributary to the regulator or diversion structure for the CSO outfalls.

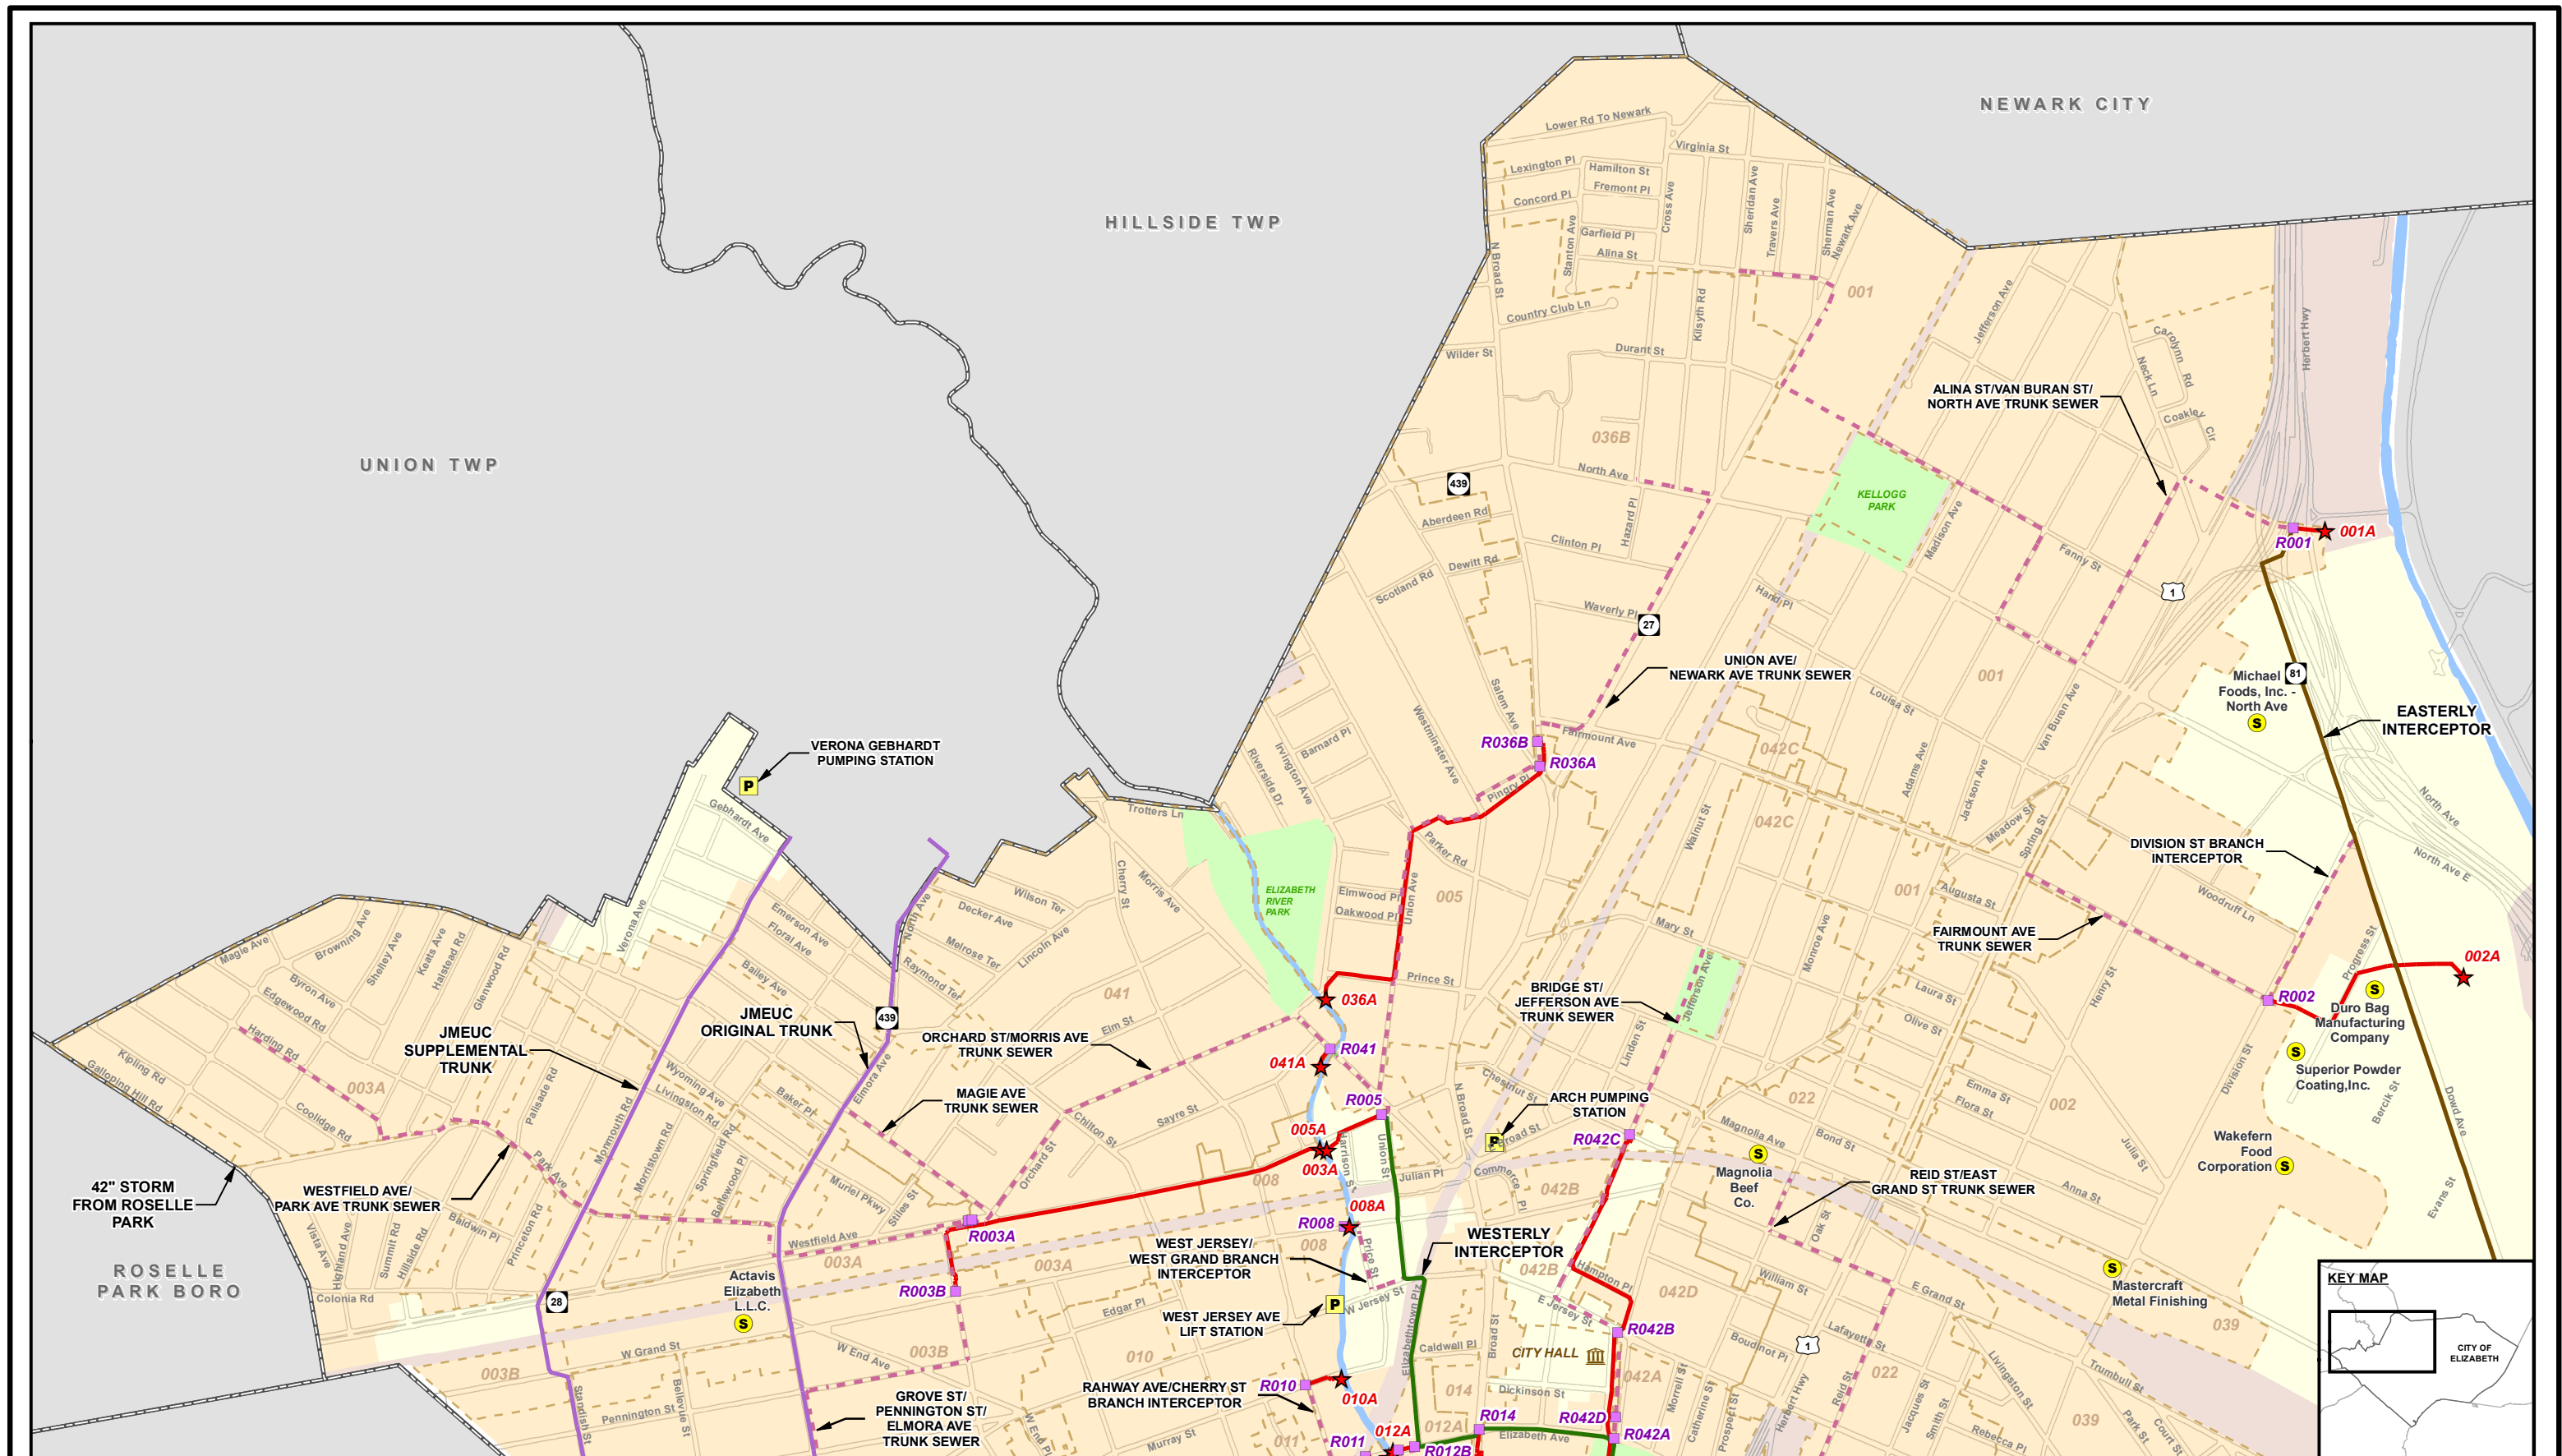

All dry weather sewage from the City sewer system is conveyed to and treated at the JMEUC WWTP. Except for flows from sewers directly connected to the Joint Meeting trunk sewers, wastewater is collected and conveyed by 2 City owned intercepting sewers serving the easterly and westerly portions of the City, respectively. These intercepting sewers flow to the Trenton Avenue Pumping Station (Trenton Avenue PS or TAPS), which is the City's main pumping station located along the west bank of the Elizabeth River in the southern end of the City and only separated by the New Jersey Turnpike from the Joint Meeting WWTP. As such, the Trenton Avenue PS discharges flows to the JMEUC incoming trunk sewer approximately 1,300 feet upstream of the wastewater treatment facilities.

During wet weather conditions, a certain amount of combined sewage is conveyed through the interceptors to the Trenton Avenue PS and pumped to the JMEUC WWTP for treatment. By the current agreement with JMEUC, the maximum average daily flow that can be discharged from the Trenton Avenue PS to the JMEUC WWTP is 18 million gallons per day (mgd) and the maximum peak flow is limited to 36 mgd. (The existing ultimate pumping capacity (all pumps running) of Trenton Avenue PS is estimated to be about 55 mgd.) Combined sewage flows in excess of the allowable pumping rate and the conveyance and storage capacities are diverted at regulator structures to the permitted CSO outfalls to the Elizabeth River, Arthur Kill and Newark Bay. Each CSO outfall is equipped with an overflow control facility to collect solids and floatables that would otherwise be discharged to the receiving waters.

In general, the major facilities of Elizabeth sewer system include:

- Approximately 160 miles of combined gravity sewer mains and trunks, with an estimated 6,400 manholes and 3,300 inlets and catch basins associated with these lines.
- Approximately 9.5 miles of separate sanitary sewers, with about 310 manholes associated with these lines.
- Approximately 38 miles of separate storm sewers, with an estimated 700 manholes and 1,700 inlets and catch basins associated with these lines.
- Twenty-nine (29) permitted CSO outfall discharge points, 38 regulator and diversion structures, and associated solids/floatables control facilities and tide gate chambers.
- Two (2) intercepting sewer lines, totaling 6.6 miles: 4.3 miles for the Easterly Interceptor and 2.3 miles for the Westerly Interceptor.
- A total of 9 pumping stations: 3 sewage pumping stations and 6 stormwater pumping stations.
- Stormwater drainage ditches and channels that convey stormwater as well as combined sewer overflows in certain locations to receiving waters.

Additional information on these facilities is given in various subsections below. Furthermore, site specific location plans and schematics, noting important dimensions, pipe sizes, and elevations, are provided in Appendix B for each combined sewer overflow outfall, regulator/diversion structure, and netting facility.

2.2 Hydraulically Connected Municipal Sewer Systems

In drafting the current NJPDES CSO Permits, the NJDEP recognized the complexity of the hydraulic interrelationships between a combined sewer system and its associated domestic treatment works and the connections from other municipal sewer systems. This complexity is further compounded by the fractured ownership of these interrelated systems and the different positions and interests each owner will have. Yet, these various hydraulically connected systems must be evaluated concurrently so that an effective and equitable CSO Long Term Control Plan (LTCP) is developed.

Through various conditions of the individual CSO permits issued to separate entities of hydraulically connected systems, the NJDEP has aimed to promote better coordination of a LTCP among permittees of hydraulically connected systems. As permittees of a hydraulically connected system, the City and Joint Meeting are cooperating and collaborating on the development of a LTCP for CSO control. The City and Joint Meeting are meeting regularly, sharing information, exchanging hydraulic models, and jointly working towards a single LTCP to address the permit requirements.

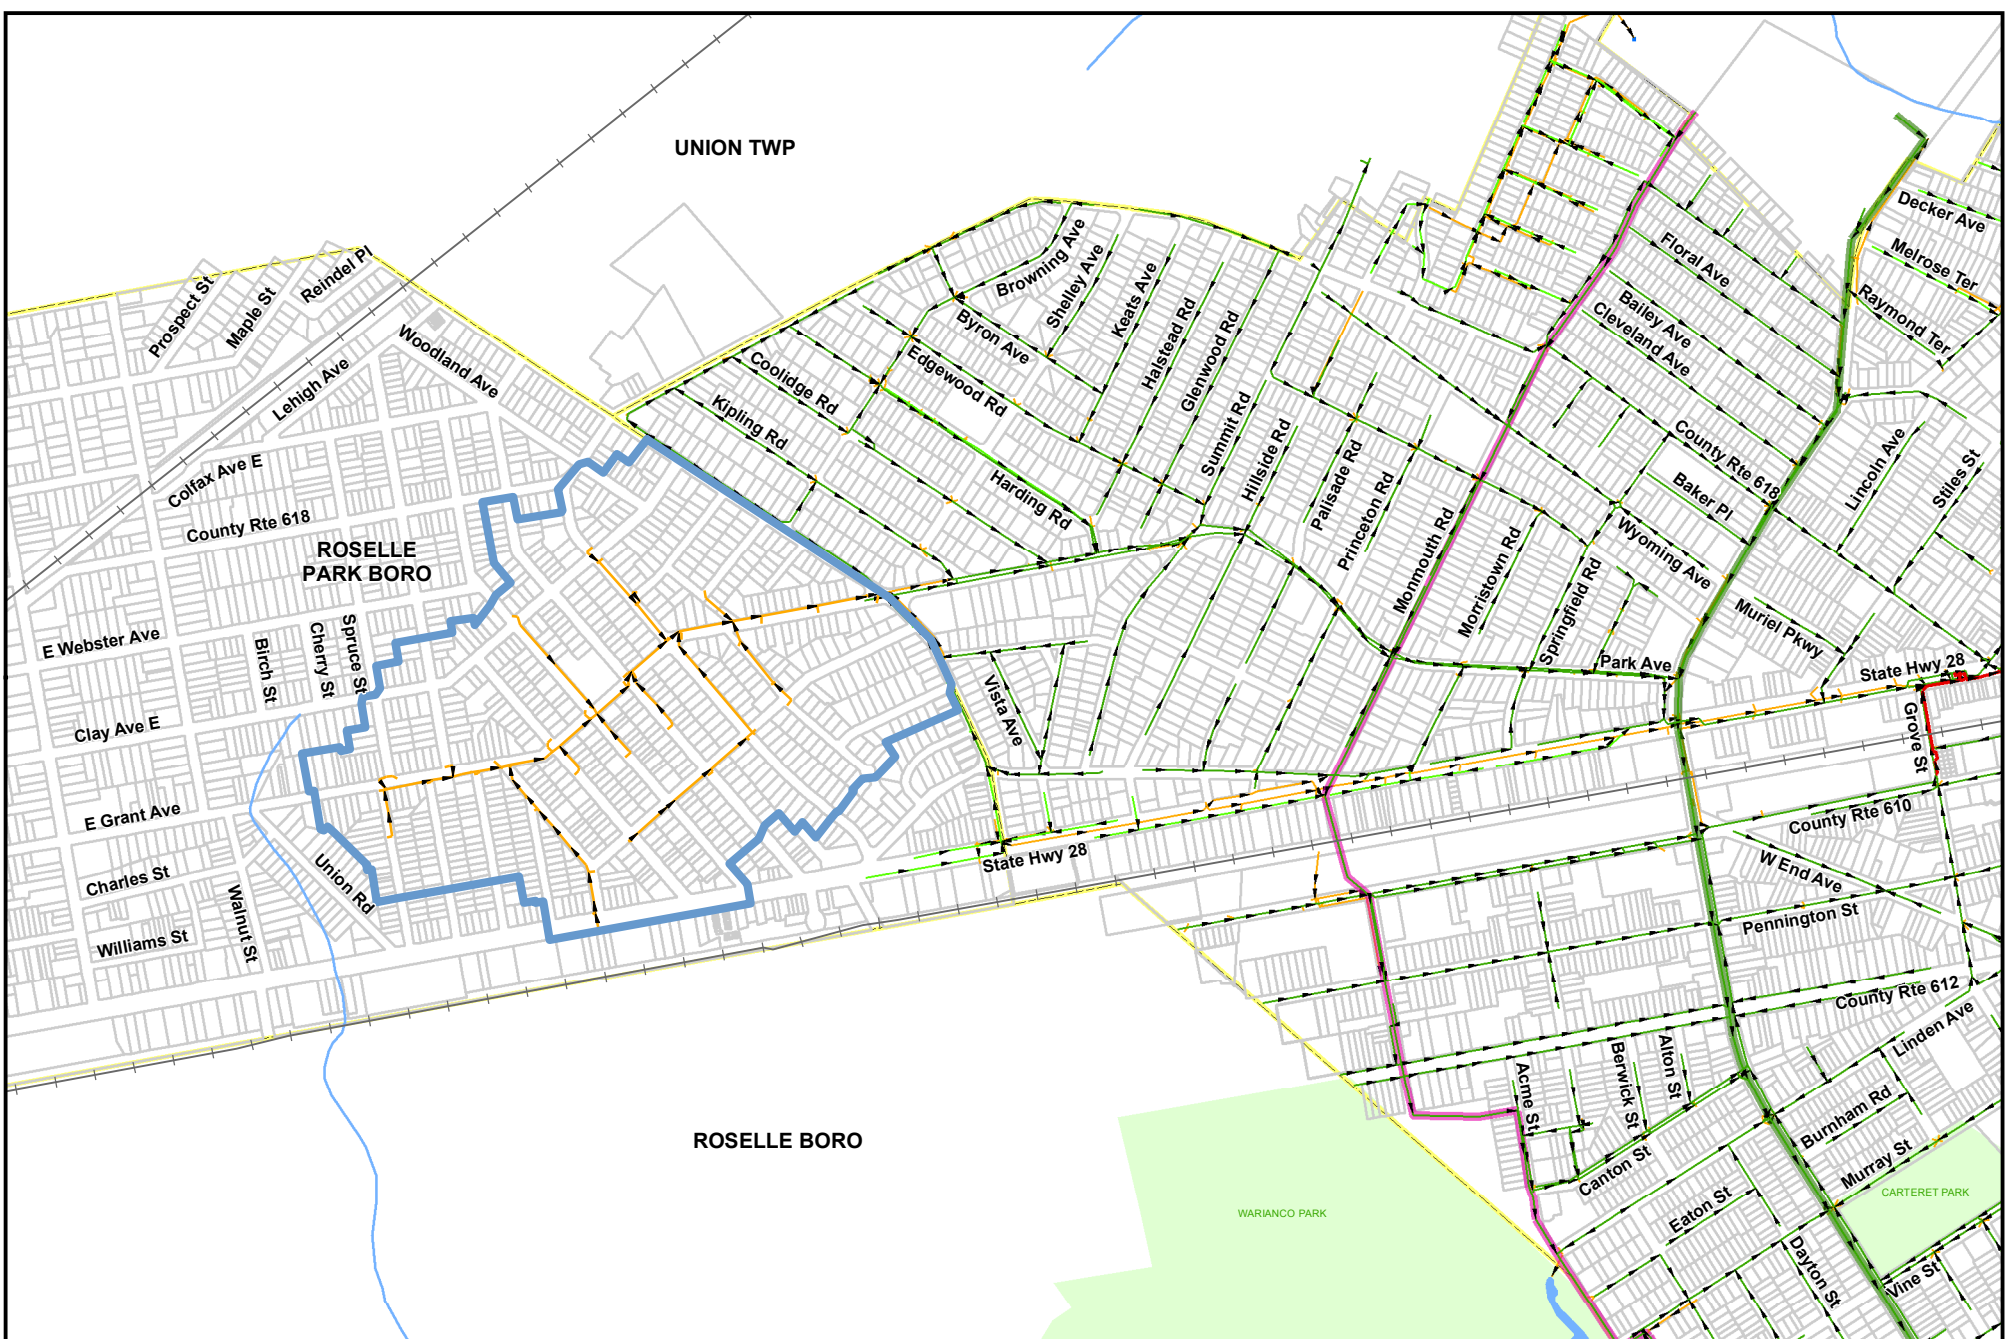

To identify the location and flow volume of inter-municipal sewer connections, the City corresponded directly with adjacent municipalities to request record plans and documents related to the sewer networks along the City of Elizabeth border. Each municipality responded and provided sewer system mapping sufficient to obtain an understanding of potential connections. The City also worked through the Joint Meeting to request record sewer information from member municipalities adjoining the City.

From a prior investigation into localized street flooding at the intersection of Park Avenue and Glenwood Road, the City became aware of a 42" diameter storm sewer from the Borough of Roselle Park connecting to the City's combined sewer system in Park Avenue along the municipal boundary at Galloping Hill Road. Flow monitoring performed from November 2012 to July 2013 showed that a significant increase in flow through the combined sewer in this area occurred during wet weather events, not in proportion to the contributing drainage area in the City. The 42" diameter storm sewer from Roselle Park was identified and its considerable impacts on the downstream stormwater drainage were noted at the time.

The City has also reviewed its available sewer mapping to find other potential significant inter-municipal connections. Various locations were identified where a local sewer crosses the municipal boundary and these locations were subsequently investigated and physically inspected. Except for the Roselle Park storm sewer on Park Avenue, the other locations are small sewers of short lengths, following local topography, and of limited tributary flow.

The City has been corresponding with the Borough of Roselle Park regarding the hydraulic connection to the combined sewer system and its impacts and responsibilities of complying with the NJPDES CSO Permit. Initial meetings were held and flow data and sewer system information has been provided to Roselle Park representatives. Roselle Park is also participating as a member of the Supplemental CSO Team to solicit input and share information on the LTCP development.

In June 2017, consultants for Roselle Park issued a draft engineering report reviewing options for the separation of the Roselle Park storm sewer from the Elizabeth combined sewer system. The report noted a storm sewer drainage area within Roselle Park of 120 acres in size as the source of the sewer flow and provided the City with a sewer layout of the area upstream of the connection, as shown in Figure 2-6. Although the report summarized a range of options, no determination on an alternative to move forward appears to have been made and the report

M M MOTT MACDONALD	CITY OF ELIZABETH UNION COUNTY, NEW JERSEY CSO LONG TERM CONTROL PROGRAM SYSTEM CHARACTERIZATION REPORT FIGURE 2-6 ROSELLE PARK PLATE				
	111 Wood Avenue South Iselin, New Jersey 08830-4112	Designed M.M.	Drawn M.M.	Checked R.C.	Approved A.G. Date 5/30/2018

remains in draft form. The draft report does recognize that the Borough of Roselle Park's storm sewer contributes to the CSO discharges to surface waters and that Roselle Park must identify a course of action and address and coordinate the associated financial implications with the City and Joint Meeting.

Temporary flow monitoring of the 42" Roselle Park storm sewer was included in the monitoring program for the current hydraulic model update and system characterization. As of December 2017, the City also has installed a flow meter at the 42" Roselle Park storm sewer connection on a semi-permanent basis to record flows entering the combined sewer system at this location. Furthermore, the City is evaluating the terms and conditions of an inter-municipal agreement for the Roselle Park stormwater discharge connection at Park Avenue, including a cost structure for a connection fee, user charges, and future construction and capital expenditures.

2.3 Receiving Waters

Brief descriptions of the receiving waters associated with the City's combined sewer system are given in this subsection. Additional information on the receiving waters monitoring and modeling work related to these receiving waters is presented in Section 6.

2.3.1 Elizabeth River

The Elizabeth River is a tributary of the Arthur Kill and flows through the City about 4 miles from north to south, crossing the municipal boundary with Hillside at Trotters Lane. The river drains a total area of approximately 23 square miles in eastern Union and southern Essex Counties, with its headwaters located in East Orange (in Essex County, NJ). Flow is tidally influenced up to about Rahway Avenue. The downstream 2-mile river segment, from the Arthur Kill to the US Route 1-9 crossing, is a trapezoidal earthen channel. Eight (8) CSO outfalls discharge to this section, which the NJDEP classifies as saline estuary waters designated use class 3 (SE3). Typical usage of SE3 waters includes: (1) maintenance, migration of fish populations, (2) migration of diadromous fish, (3) maintenance of wild life, (4) secondary contact recreation, and (5) any other reasonable uses.

Flow in the upstream 2-mile river segment, from US Route 1-9 to the municipal line, is contained in a 40-foot wide concrete flume that winds through the City's commercial center. Thirteen (13) CSO outfalls discharge to this section, which the NJDEP classifies as SE3 downstream of the Broad Street bridge and as freshwaters category 2, non-trout supporting (FW2-NT) upstream. FW2 indicates fresh water with salinity less than 3.5 parts per thousand at high tide, not designated as FW1 or Pinelands Waters. The NT classification indicates not suitable for trout maintenance.

2.3.2 Arthur Kill

The Arthur Kill is a 15-mile tidal marine waterway that connects Newark Bay and Raritan Bay, and forms part of New York/New Jersey boundary. It is a busy commercial shipping passage critical to the Port Authority of New York and New Jersey facilities in the area. A 400 to 600-foot wide shipping channel is maintained in the 500 to 600-foot wide Kill. As part of a harbor deepening project, the waterway is being deepened to a depth of 50 feet to accommodate larger container ships carrying full loads. Flow direction alternates in response to the tide. CSO Outfalls 030A, 031A, 032A and 037A discharge to the Kill. The NJDEP classifies the section of the Kill which bounds the City as SE3.

2.3.3 Newark Bay

The 5-mile long, 3,000 to 6,000-foot wide, tidal Newark Bay provides the outlet to the Hackensack and Passaic River. Two of the nation's largest shipping ports, Port Elizabeth and Port Newark, line the western bank. Flow direction alternates in response to the tide. The NJDEP classifies Newark Bay as SE3. The outfalls discharging to Newark Bay are 001A (via the Peripheral Ditch stormwater drainage channel), 002A (via the Great Ditch drainage channel), 039A (via the Great Ditch drainage channel), and 034A.

2.3.4 Stormwater Drainage Ditches

The Peripheral Ditch and the Great Ditch are the main drainage ditches that convey stormwater from the eastern areas of the City to Newark Bay. These drainage ditches also serve to convey discharges from 3 CSO outfall points in the City of Elizabeth to the Newark Bay receiving waters. Historical mapping shows that much of the area east of Trumbull Street and south of US Route 1-9 was essentially marshland prior to the extensive development of the area for industrial and railroad use and that now includes the Newark Liberty International Airport, Port Elizabeth Marine Terminal, New Jersey Turnpike, and Jersey Gardens facilities. The Peripheral Ditch and the Great Ditch are manmade conveyance systems constructed to drain these marshlands and to allow its development. These ditches incorporate open earthen channels, closed conduits, culverts, and a pump station that were built and are being used to collect and drain stormwater. While the CSO Permit notes these drainage ditches as receiving streams, the Peripheral Ditch and the Great Ditch are not classified as surface water resources in the NJDEP surface water quality standards and no use designations are indicated. The Peripheral Ditch and Great Ditch are therefore characterized as stormwater conveyance facilities to the Newark Bay receiving waters.

The Peripheral Ditch was constructed around the current configuration of Newark Liberty International Airport. It passes through both Newark and Elizabeth and extends on the west side of the airport, south into Elizabeth, then turns north on the east side of the airport to the Elizabeth Channel. At this point, the Peripheral Ditch drains into Newark Bay, either by gravity through tide gates or by pumping via the Newark Meadowlands Stormwater Pumping Station when tides do not allow for gravity flow. The operation of the pumping station calls for the Peripheral Ditch to be pumped down in advance of large storm events, allowing for the tributary areas to drain into it, and pumping is to continue during the rainfall event. The City of Newark is responsible for the operation of the pumping station. Stormwater from a large drainage area and discharges from 5 CSO outfalls from the City of Newark flow into the Peripheral Ditch, along with stormwater and 1 CSO outfall from the City of Elizabeth. In addition, stormwater drainage from Newark Liberty International Airport is tributary to the ditch.

The Great Ditch starts by running approximately 1,400 feet southerly as an open drainage channel through private properties between Dowd Avenue and the New Jersey Turnpike exit 13A toll plaza to a culvert under Sullivan Road. The drainage ditch then continues about 1,400 feet to a series of closed pipes and culverts crossings under the New Jersey Turnpike interchange and main throughway. The crossings under the interchange include a 36" diameter pipe and a 108" diameter culvert. The 36" diameter pipe continues across the main Turnpike throughway, along with a 72" diameter culvert. The distance along these culverts is about 1,200 feet. A short section of open ditch then exists in the area north of the end of Schiller Street before the drainage system crosses under a roadway and the Conrail tracks for about 500 feet with 36" and 60" diameter pipes to a junction chamber, then a 91" square box culvert to another chamber, and then a 72" square box culvert. From the east side of tracks, the Great Ditch drainage enters a 10-foot diameter pipe running approximately 4,800 feet through the Jersey Gardens development parcels to its Newark Bay outlet.

2.3.5 General Topography

The City can be divided into three main topographic zones. The southern zone slopes to the Arthur Kill and Newark Bay, with some drainage to the Elizabeth River, and is generally bounded on the north by the New Jersey Turnpike. The ground varies in elevation from 30 feet above sea level at the Turnpike to sea level at the waterfront.

The eastern zone is separated from the western zone by a ridge extending from the New Jersey Turnpike northward along Elizabeth Avenue to Seventh Street and then northerly to the Hillside-Newark border and it drains through the conveyance channels of the Peripheral and Great Ditches to Newark Bay. The ridge ranges in elevations from 25 feet above sea level at Sixth Street to over 45 feet at the Conrail railroad. From this ridge, the ground slopes at about 0.5% to the east for about 1 mile to the low-lying areas developed for the Newark Liberty International Airport, the Port Elizabeth Marine Terminal, and the Jersey Gardens commercial zone.

The western zone includes the remainder of the City and is drained by the Elizabeth River which splits the zone from north to south. Ground surfaces are below Elevation 50 in all but the northwestern corner of the City, where ground surfaces approach Elevation 90.

The low-lying areas adjacent to the Elizabeth River are protected by the Elizabeth River Flood Control Project (ERFCP). North of US Route 1-9, the Elizabeth River rises slightly, but drainage of tributary areas is complicated by the presence of transverse ridges. There are 2 such cross ridges on the eastern slope and 4 on the western. The ridges generally increase in elevation from south to north and from east to west, reaching an elevation of about 90 feet above sea level in the northwestern corner of the City. The cross valleys do not drain uniformly to the Elizabeth River, but contain certain low points. Low points occur in other areas, but they are most frequent in the northern part of the western drainage zone.

2.4 Project Area Population and Demographic Trends

Historical population data from the United States Census Bureau is provided in Table 2-2 for the City of Elizabeth and Union County overall. The 2016 population, which is the latest estimate available from the Census Bureau as of this report date, for the City is 128,640 persons. This current population represents an increase of 22,439 persons, or 21.1%, from the low point of the past several decades in 1980.

Table 2-2: Historical Population Data

Year	City of Elizabeth		Union County		Population Ratio
	Population	Change from Prior	Population	Change from Prior	Elizabeth to Union County
1970	112,654	-	543,116	-	0.207
1980	106,201	-6.08%	504,094	-7.74%	0.211
1990	110,002	3.46%	493,819	-2.08%	0.223
2000	120,568	8.76%	522,541	5.50%	0.231
2010	124,969	3.52%	536,499	2.60%	0.233
2016 (estimate)	128,640	2.85%	555,630	3.44%	0.232

Source: United States Census Bureau

A comparison with the decennial population data for Union County as a whole shows that the City's decline was less severe and recovered earlier in the 1970 to 1990 period and has increased at a higher pace through 2010. As a result, the City's population has become a

greater fraction of the total Union County population since 1970, with a current value of approximately 23.3%.

Population projections for Union County are available from the State of New Jersey Department of Labor and Workforce Development. Using these projections and assuming a constant 23.3% fraction for the Elizabeth population, it can be roughly estimated that the City's population may grow to 143,200 persons by Year 2034, which equates to an 11.3% total increase from the 2016 population, or 0.6% annually over 18 years.

Using the 2010 Census Bureau data, the City's population density is 10,144 persons per square mile (ppsm), compared to Union County overall at 5,216 ppsm and New Jersey overall at 1,196 ppsm. According to data available from the City of Elizabeth Master Plan Report (October 2005, Land Use Plan Update January 2016), the median age in the City is 32.5 years, while it is 38.0 years in Union County. The City has relatively higher distributions in the under 5 years and 20-34 years cohorts, whereas the County has a higher percentage in the 40 to 59 age groups. Regarding household size, the largest number of households consist of 4 or more persons for both the City and the County, with the total number of housing units being 39,273 and 185,688 and the average household size being 3.23 and 2.94, respectively. The median household income is \$43,966 and \$69,396 for the City and Union County, respectively, indicating a 57.8% difference.

The City's population figures reflect overall demographic trends within New Jersey. It appears that the populations within the outer-ring suburbs surrounding the New York and Philadelphia metropolitan regions have been declining over the last several years, while municipalities in closest to the cities, particularly in the northern half of the state, have experienced renewed growth. Persons in the retirement age cohorts have been leaving the State, while younger age cohorts have been moving into older communities that have the infrastructure in place to support walkable downtowns with accessible mass transit to the metropolitan business centers. Based on available statistics, it appears that Elizabeth is attracting a number of young families, both with and without young children.

2.5 Land Use and Zoning

Figure 2-7 presents the 2012 (updated 2015) NJDEP geographic information system (GIS) land use dataset for the City of Elizabeth. The detailed classifications provided by the NJDEP were recategorized into more generalized groups. Table 2-3 lists the reclassification scheme utilized and Figure 2-7 depicts the reclassified land uses within the City.

The land use classes within the CSO drainage basins were extracted from this data and are summarized in Table 2-4, which provides the basin area in acres and the percent distribution for each land use reclassification category and the corresponding relative degree of impervious surface coverage. The percent impervious cover is an aggregate value estimated from the breakdown of land of different coverage categories given in the NJDEP dataset. Table 2-4 also provides a comparison between the 2012 and 2007 land use data to indicated the degree of development changes within the period.

The City is highly urbanized and densely populated, with a population density of 10,144 ppsm within approximately a total of 12.3 square miles (7,885 acres) per the 2010 Census Bureau data, as noted in Section 2.4.

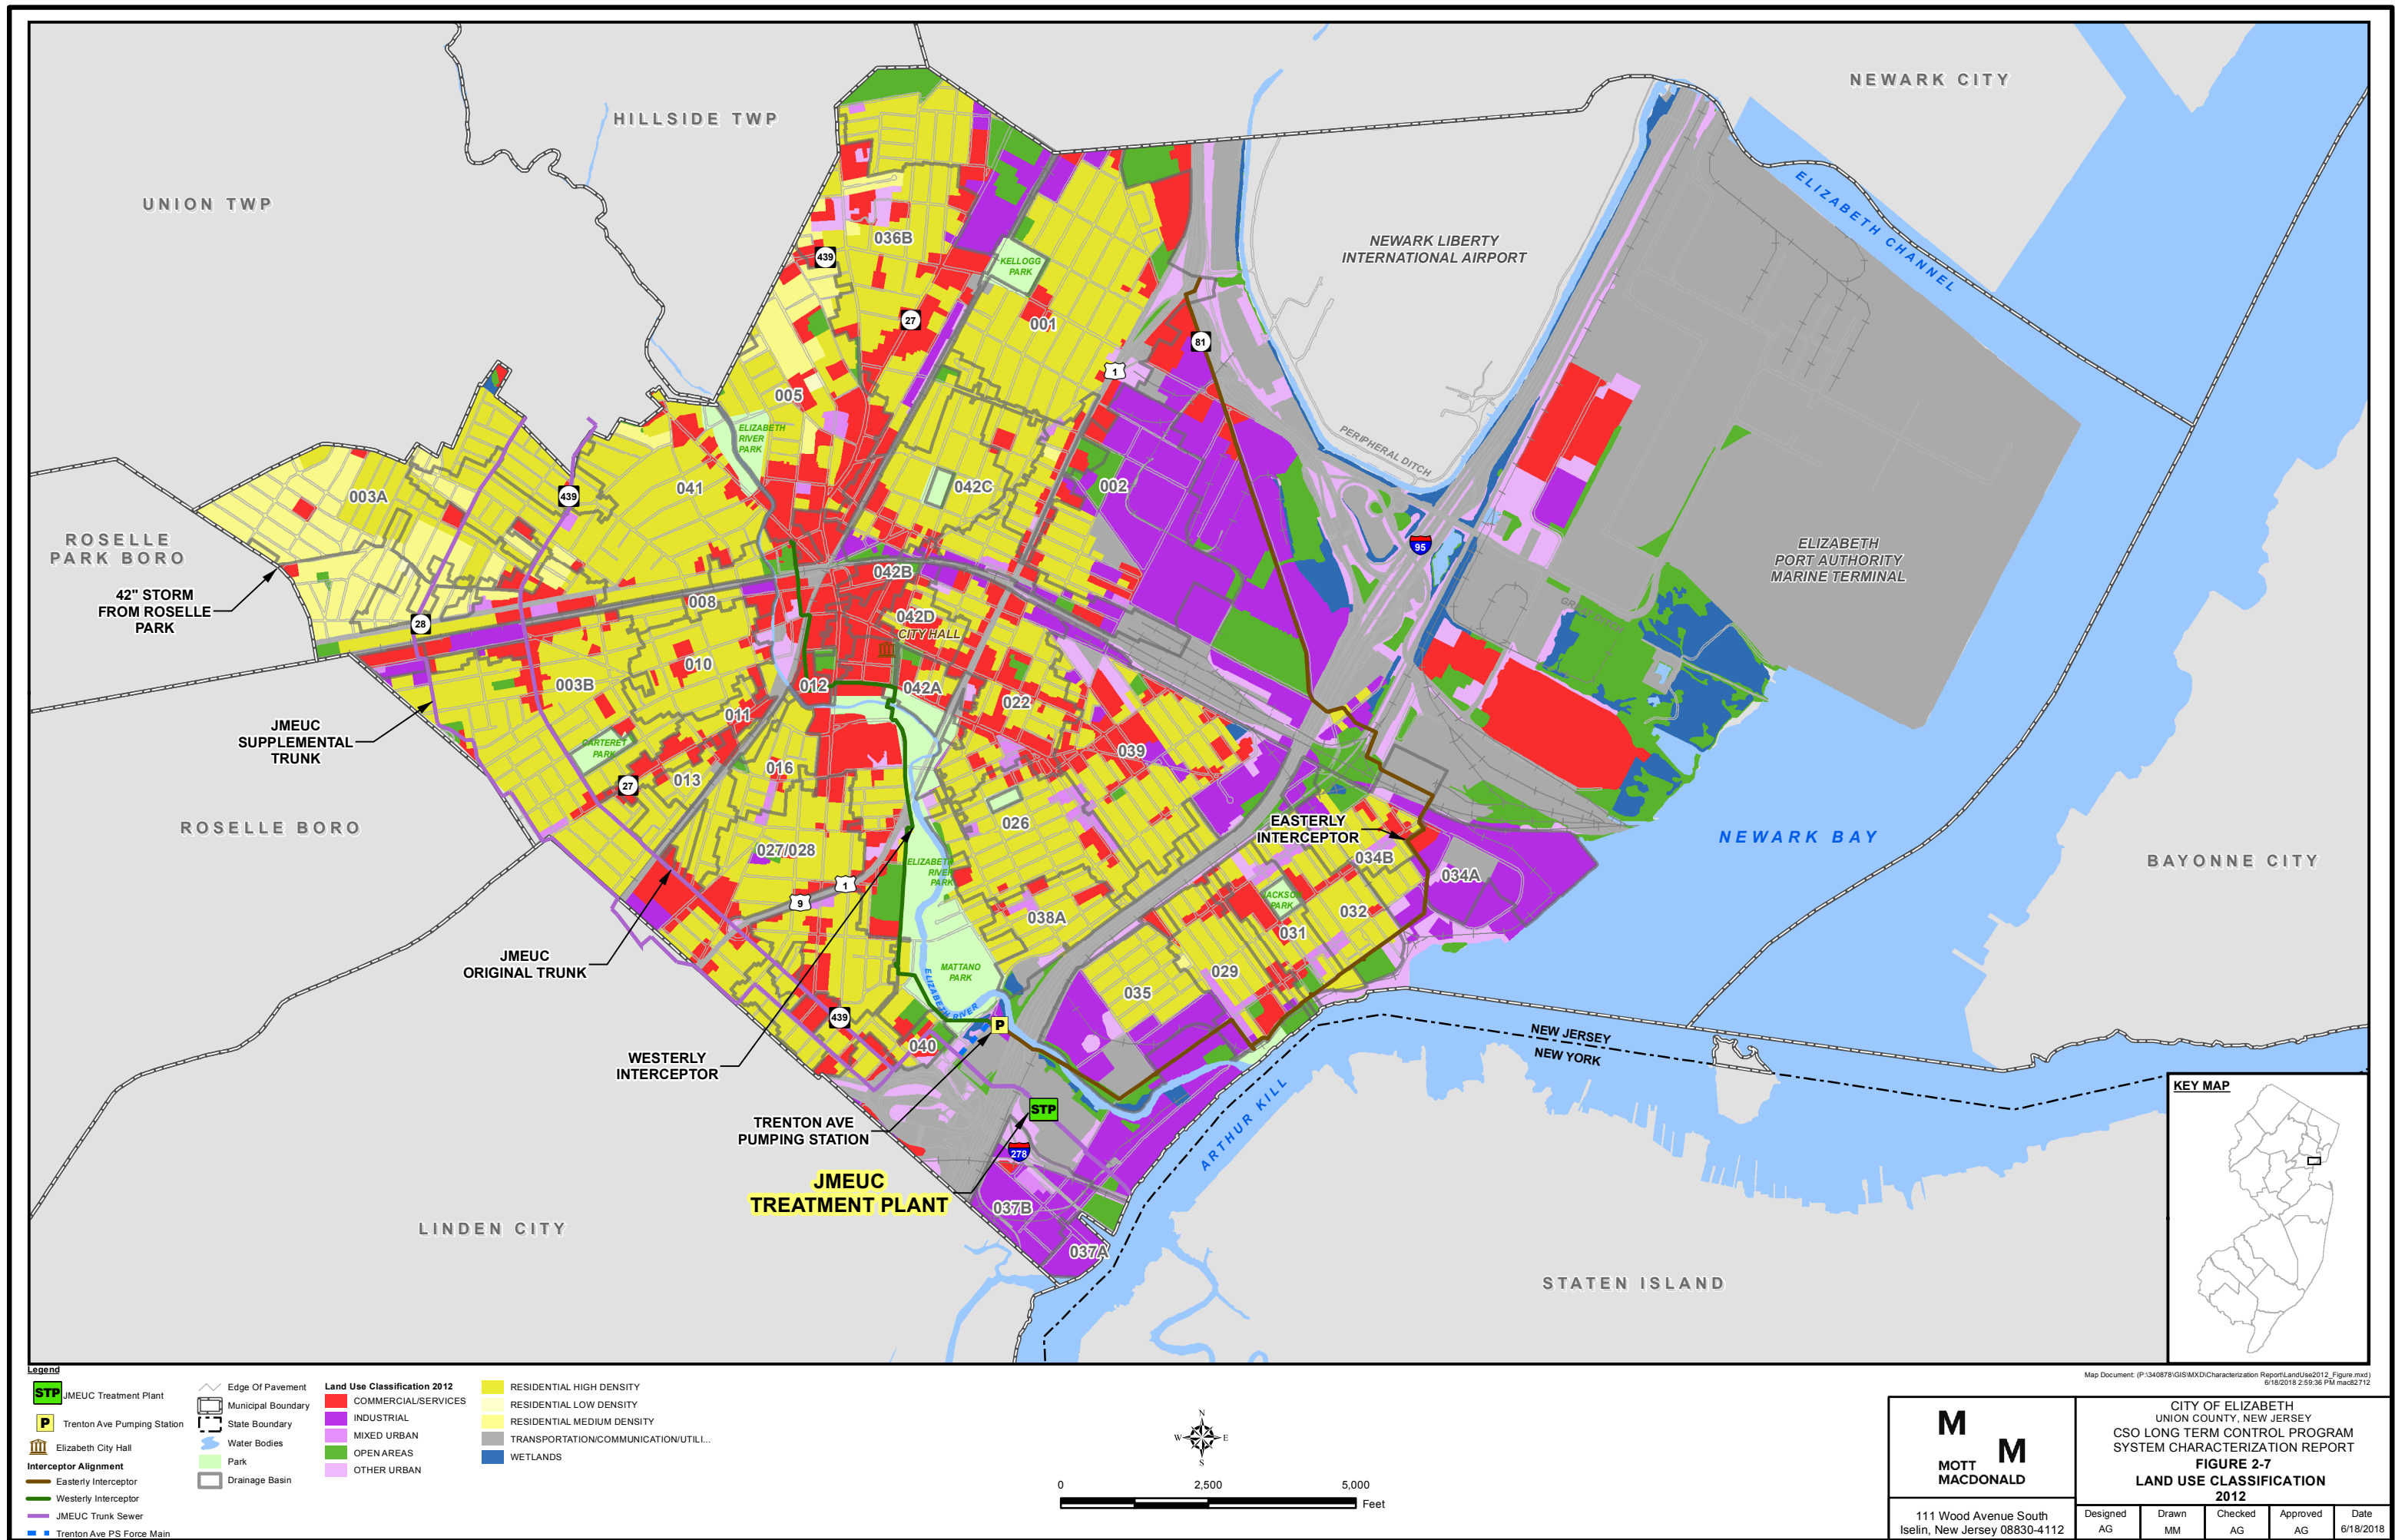

Table 2-3: Land Use Reclassification

2012 NJDEP Land Use Classifications	Reclassification Category
Altered Lands	Wetlands
Artificial Lakes	Open Areas
Athletic Fields (Schools)	Open Areas
Bridge over Water	Transportation
Cemetery	Other Urban
Commercial/ Services	Commercial
Deciduous Brush/Shrubland	Open Areas
Deciduous Forest (>50% Crown Enclosure)	Open Areas
Deciduous Forest (10-50% Crown Enclosure)	Open Areas
Deciduous Wooded Wetlands	Wetlands
Dredged Lagoons	Open Areas
Herbaceous Wetlands	Wetlands
Industrial	Industrial
Major Roadway	Transportation
Managed Wetland and Built Up Recreation Area	Wetlands
Military Installations	Commercial
Mixed Transportation Corridor Overlap Area	Transportation
Mixed Urban or Built-Up Land	Mixed Urban
Old Field	Open Areas
Other Urban or Built Up Land	Other Urban
Phragmites Dominate Old Field	Wetlands
Railroads	Transportation
Recreational Land	Open Areas
Residential High Density or Multiple Dwelling	Residential High Density
Residential Rural Single Unit	Residential Low Density
Residential Single Unit Low Density	Residential Low Density
Residential, Single Unit Medium Density	Residential Medium Density
Saline Marsh	Wetlands
Stormwater Basin	Open Areas
Streams and Canals	Open Areas
Tidal Rivers, Inland Bays, Other Tidal Waters	Open Areas
Transitional Areas	Open Areas
Transportation/Communication/Utilities	Transportation

Different patterns of land use can be seen from Figure 2-7. The western portion of the City is dominated by high density residential, with a mix of other intensity residential and commercial uses. Most commercial uses are grouped around major transportation corridors including the Amtrak / NJ Transit commuter rail line, US Route 1-9, and Broad Street. The eastern border of the City is dominated by transportation uses, such as Newark Liberty International Airport and Port Elizabeth. There are certain groupings of industrial uses scattered within the northern, central, and southern portions of the City.

Table 2-4 shows that on a composite (i.e., percent total) basis for the 2012 land use data, the combined sewer system area can be characterized as approximately 52.2% high density residential, 8.2% medium density residential, 0.1% low density residential, 17.3% commercial, 11.6% industrial, 3.5% open areas, 3.3% transportation, 1.7% mixed urban, 1.9% other urban,

Table 2-4: Land Use by CSO Drainage Basin, 2012 and 2007 Comparson

CSO Basin Sub-Basin	Area (acres)	Data Set	Land Use / Land Cover (% by area)										Impervious Cover (%)

and 0.2% wetlands. The composite impervious cover for the combined system sewershed is about 62%.

The values in Table 2-4 do not include the 120 acres in Roselle Park tributary to the 42" storm sewer that connects to the City's CSS at Park Avenue. The Roselle Park storm sewer contributing area increases the area related to CSO Sub-basin 003A by the corresponding value. Land use in the Roselle Park storm sewer tributary area is similar to the adjoining City of Elizabeth area, being predominately medium and high-density residential with some commercial and mixed urban uses.

A comparison between the 2012 and 2007 composite land use distributions notes that the distribution has remained mostly unchanged for the period, with a slight decrease in the industrial and other urban categories and a small increase in open areas. The distributions for each CSO basin are also relatively unchanged, along with the impervious coverage values. There have been some shifts between land uses in CSO Basins 001, 002, 011, 013, 021, 037, 038, 041, and 042, most notably with Basin 037 having 13% moving from other urban to open areas and industrial uses and land use changes in the small Basins 021 (2.8 acres) and Sub-Basin 038B (5.8 acres).

As part of its master planning process, the City analyzes current land uses and permitted uses to better understand and evaluate the need to change the permitted uses in the existing zones and to introduce new zoning designations. Elimination of zoning designations that have not been utilized or have disappeared over time are considered, as well as the introduction of new zoning districts that have the potential to increase economic development and bring land use ordinances in line with current goals and objectives. A re-examination report of the Land Use Element of the Master Plan was published in January 2016, proposing revisions to the zoning map and amendments to the land use development regulations, which were subsequently adopted.

Table 2-5 lists the adopted zoning districts of the City of Elizabeth, corresponding to the locations and boundaries depicted on the zoning map, revision date April 26, 2016. Figure 2-8 is reduced scale image of the City zoning map, as produced by Harbor Consultants (Cranford, NJ) and accessed online at <http://www.elizabethnj.org/engineering-division>.

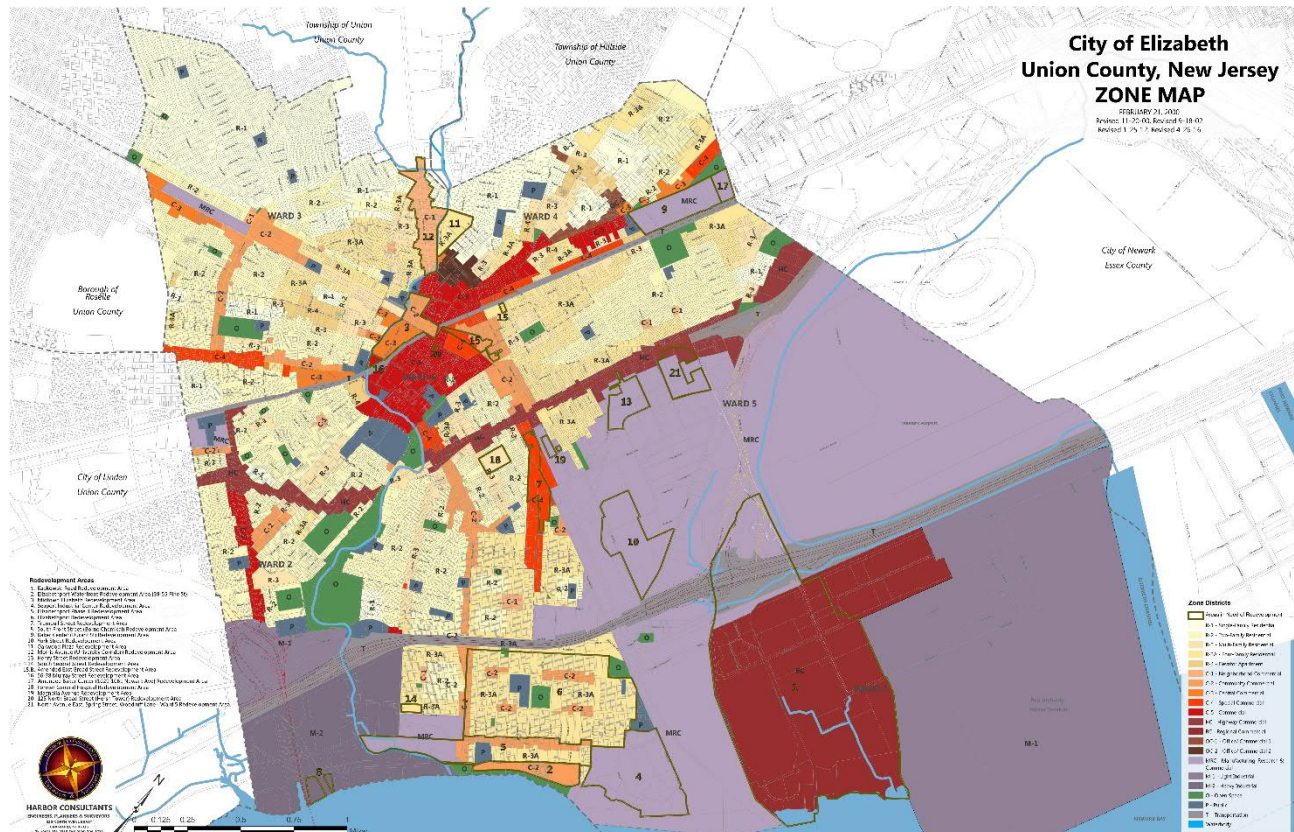

Table 2-5: Zoning Districts and Designations

Description	Designation
Single-family residential zone	R-1
Two-family residential zone	R-2

Figure 2-8: Zoning Map

Source: Harbor Consultants (Cranford, NJ), revision date April 26, 2016.

There are 5 residential zones located throughout the City: R-1, Single Family Residential; R-2, Two-Family Residential; R-3, Multifamily Residential; R-3A, Four-Family Residential; and R-4, Elevator Apartments. Permitted residential uses are summarized in Table 2-6.

There are also 9 commercial zones interspersed throughout the City; C-1, Neighborhood Commercial; C-2, Community Commercial; C-3, Central Commercial; C-4, Special Commercial; C-5, Commercial Zone; OC-1, Office Commercial-1; OC-2, Office Commercial-2; RC, Regional Commercial; HC, Highway Commercial Zone. Permitted uses for each of these commercial zones are summarized in Table 2-7. In the C-5 commercial zone, residential units with a minimum net floor area of 850 square feet and a maximum of 2 bedrooms per unit are permitted above first floor permitted uses. Per the 2016 re-examination report, OC-1 zone encourages the preservation of classic older residential structures along Newark Avenue and North Avenue, where feasible, for office use which is compatible with uses on the opposite sides of these avenues. The OC-2 zone was created to encourage the mix of office and commercial uses with low intensity residential development and allows residential uses provided that no site is

developed with more than 12 residential units and all open space and off-street parking requirements are satisfied. The RC zone permitted uses are major retail and commercial uses and major office buildings with gross floor area of not less than 25,000 square feet. The HC zone is intended to promote services, retail uses and commercial activity along mostly the Route 1-9 corridor and allows residential apartments on second and third floors only.

The City currently has 3 manufacturing and industrial zones: M-1, Light Industrial; M-2, Medium Industrial; and MRC, Manufacturing, Research, and Commercial. Table 2-8 summarizes their permitted uses. MRC zone permitted uses include corporate business and professional offices; research laboratories; large scale retail consistent with C-2 zone uses; light manufacturing; general commercial uses; and indoor amusement facilities.

Table 2-8: Permitted Manufacturing and Industrial Uses

Type of Use	Zone Designation		
	M-1	M-2	MRC

Per the 2016 master plan land use element re-examination report, the City has adopted separate zoning districts for Open Space, Public Space, and Transportation. The Open Space (O) zone district is designed to contain improved and unimproved publicly owned open space, while publicly owned buildings, land and other institution areas are contained the Public Space (P) Zone District. The Transportation (T) Zone District encompasses publicly owned tracts of land in the City which are utilized for public transportation. The Transportation Zone District was created to establish a separate zone for publicly owned street rights-of-way and transportation rights-of-way.

The 2016 master plan land use element re-examination report further notes that the Port Authority plays a key role in the land use patterns. The expansion of the Newark Liberty International Airport and Federal Aviation Administration (FAA) rules and guidelines on flight patterns, cargo, flight crews and other business operations at the airport impact supporting land uses in the City such as hotels, parking lots, nearby commercial establishments and restaurants. Increasing shipping activity at the Elizabeth Port Authority Marine Terminal is also expected with ongoing improvements to the Goethals Bridge, Bayonne Bridge, and the waterway navigational channels. These transportation and shipping centers influence adopted and proposed redevelopment programs, as reflected by recent construction of warehousing facilities near the Elizabeth Marine Terminal and a number of new hotels constructed near the airport.

2.6 History of Major Sewer System Developments

This subsection presents a brief history of the major developments of the Elizabeth sewer system. This information has been obtained from various sources, including previous characterization reports prepared in response to the National CSO Control Policy and related regulatory permit authorizations.

In the nineteenth and early twentieth century, the City of Elizabeth constructed branch sewers in nearly all its then developed streets. The branch sewers collected both sanitary wastes and storm runoff in a common pipe that discharged into trunk sewers which extended to the waterways. Most branch sewers from this period are 8" to 18" diameter vitrified clay pipe (VCP) with joints at 2 or 3-foot spacing. Most trunk sewers are larger than 18" diameter and constructed of brick masonry and egg shaped, with an invert cunette diameter typically equal to one-half of sewer's maximum width.

In 1898, the Joint Meeting of Essex and Union Counties was created to reduce pollutant discharge to waterways and provide treatment for sewage from municipalities within its service area. Joint Meeting constructed the Original Trunk sewer from 1901 to 1904, which provided a discharge to the Arthur Kill for its member municipalities. With the area's growth, it was determined that additional conveyance capacity was needed and JMEUC constructed the Supplemental Trunk sewer from 1926 to 1936. At this time, the JMEUC also constructed a primary treatment plant in the Bayway section of the City of Elizabeth and the discharge of raw sewage was discontinued. In the 1970s, the Joint Meeting treatment plant was upgraded and expanded to secondary treatment and sludge dewatering facilities were placed into service in the 1992.

With the construction of the Joint Meeting facilities, dry weather flows (DWF) from the westerly side of the City were diverted to the Joint Meeting WWTP in the 1930s, eliminating much of the raw sewage discharge to the Elizabeth River. This was accomplished by constructing new sewers associated with the City's Westerly Interceptor, branch interceptors, and a pump station at Clarkson Avenue and Britton Street (which was abandoned in the 1950s with subsequent system improvements). In the 1950s, the Trenton Avenue Pumping Station, the Easterly Interceptor and a new section of the Westerly Interceptor were constructed to collect and convey all dry weather sanitary flow to the Joint Meeting WWTP. With the interceptor installations, regulators were constructed on the outfall lines to intercept each of the outfall pipes to convey DWF to the interceptors, and permit overflow only to be conveyed to the waterways during wet weather conditions when the capacity of the interceptor was exceeded.

Prior to the National CSO Control Policy of 1994, the City implemented an extensive CSO abatement program in the 1980s that involved the construction of sewer flushing and storage modules, installed on existing sewers to capture for treatment a part of the first flush flow during wet weather events. Flushing modules were located upstream of sewer reaches that were considered too flat to effectively transport the solids in dry weather flow, resulting in solids deposition. A flap gate in the flushing module was designed to close once during each night when flows are low and automatically open when the stored sewage volume rose to a preset level needed to create a flushing wave adequate to resuspend and transport the deposited sewage solids to the interceptor at a flow rate that would not cause overflow at the downstream overflow control regulators. Without the flushing modules, the deposited solids would have been resuspended during wet weather and discharged to the waterway by flows which exceed the capacity of the downstream conveyance facilities.

In-line storage modules were designed to temporarily store and divert to treatment most of the flow from small rainfalls and part of the first flush of large storms. The amount of first flush flow

diverted depended on the volume of the storage and the intensity of the rainfall. The dry weather and small rainfall flows were diverted around the closed gate by gravity or pumped to treatment. Wet weather flows which exceeded the capacity of the diversion sewer were stored behind a closed flap gate. When the storage level rose to a preset high level, the flap gate opened automatically allowing stored combined sewage to discharge to a receiving waterway. The flap gate automatically closes when the flow returns to a preset low level.

A total of 11 sewer flushing modules and 12 in-line storage modules were constructed, but these modules have all since been deactivated due to various problems that affected their operations, including faulty electronic equipment caused by humidity in the underground chambers, flap gate shaft failures, and hydraulic power unit and auxiliary equipment failures.

In early 2000s, the City completed the construction of numerous CSO Solids/Floatables (S/F) Control Facilities per the provisions of the National CSO Control Policy and associated NJPDES permit actions for the removal of solids and floatables larger than 1/2" from CSO discharges.

In many areas of the City, separate storm relief sewers have been added to alleviate flooding, which also has reduced the area served by combined sewers and reduced CSOs to the receiving water bodies. In certain developed areas, large stormwater runoff relief sewers were constructed to supplement combined sewers and relieve local flooding issues. Relatively new separate sewer facilities were constructed in the 1990s in the northeastern portion of the City to support the commercial and industrial development there. Accordingly, the system is comprised of a variety of different pipe shapes and materials as well as manholes, regulator chambers, combined sewer outfalls, siphons, pumping stations and CSO netting facilities.

The City has and continues to implement many significant sewer system capital improvement projects related to regulatory compliance, system renewal, and flood control and protection. Such projects included the Combined Sewer Overflow Solids/Floatables Control Facilities, the Verona-Gebhardt Flood Control Project, the Mid-Town Area Utility Improvements, and the Elizabeth River flood control facilities restoration program.

2.7 Sewer System Components

In this subsection, information on the various components of the City of Elizabeth sewer system, particularly the features integral to the combined sewer system structure and responses to wet weather events, is highlighted and discussed. Emphasis has been placed on presenting data compiled and analyzed from available documents and provide insight to the existing combined sewer system characterization.

2.7.1 Combined Sewer Overflow Outfalls

The City of Elizabeth has 29 authorized CSO outfall discharge locations per the current NJPDES CSO Permit. Several CSO outfalls have been eliminated over the years through outfall consolidation and sewer separation work. Accordingly, the remaining number of CSO outfalls is significantly less than the highest outfall discharge serial number assigned by the CSO Permit.

Table 2-9 tabulates various characteristic for each CSO outfall discharge point, including the permit serial discharge number and outfall name; location coordinates; receiving water; pipe size, shape, and invert elevation; interceptor district; Elizabeth River Flood Control Project (ERFCP) data, where applicable; presence of storm connections on outfall downstream of regulator; and potential tidal influence. Appendix B includes a large-scale location plan for each outfall, along with schematic details for regulator/diversion structures, and netting chambers.

Table 2-9: Combined Sewer Overflow Outfall Summary

¹ * and light shading indicates relief outfall designation.

² Relative to observer facing downstream towards mouth of river at Arthur Kill.

The permitted CSO outfalls have been further classified as either primary or relief outfalls, with relief outfalls being designated where the sewershed has an interconnection to another downstream sewershed with a subsequent regulator and outfall network. The 8 relief outfalls are indicated in Table 2-9 with an asterisk adjacent to the outfall number and light shading. The relief outfalls and the associated relieved sewersheds are as follows:

- Relief Outfall 003A, Westfield Avenue and Magie Avenue, relieving Relief Outfall 041A and Primary Outfall 005A. (Westerly Interceptor.)
- Relief Outfall 021A, Spring Street / Third Avenue, relieving Primary Outfall 022A. (Westerly Interceptor.)
- Relief Outfall 030A, Front Street/East Jersey Street, relieving Primary Outfall 029A. (Easterly Interceptor.)
- Relief Outfall 036A, Orchard Street / Dod Court, relieving Primary Outfall 005A. (Westerly Interceptor.)
- Relief Outfall 038A, Third Avenue, relieving Primary Outfall 035A. (Easterly Interceptor.)
- Relief Outfall 039A, Trumbull Street / Fourth Street, relieving Primary Outfall 034A. (Easterly Interceptor.)
- Relief Outfall 041A, Morris Avenue / Sayre Street, relieving Primary Outfall 005A (Westerly Interceptor.)
- Relief Outfall 043A, Army Corps Flood Control Structure, relieves Primary Outfall 035A (Easterly Interceptor.)

These relief outfalls may be influenced by water levels in upstream reaches of the connected adjacent sewershed.

Furthermore, it can be noted that Outfalls 008A, 012A, 014A, and 016A are associated with relatively small drainage areas partially served by separated storm sewers. These combined sewersheds are connected to the Westerly Interceptor and given the small associated tributary areas, these combined sewers may be candidates for full separation in the future.

Consideration of Potential Outfall Impacts

Each of CSO outfall networks, including the outfall pipe, solids/floatables control facilities, and regulators, were evaluated for potential adverse impacts corresponding to overflow / weir elevations within the tidal variations; stormwater connections to the CSO outfall downstream of regulator/diversion structures; and outfalls also utilized for ERFCD drainage structures. These potential impacts are noted and summarized in Table 2-9. The potential effects of these situations on the CSO outfalls are described below.

Tidal Influence

Outfalls where the overflow weir elevation is within the normal daily tide variations are potentially subject to inflow entering the sewer system from the receiving stream backwater. This can occur where the tide gate does not fully close, either from depositions blocking the gate, or from foreign material. Therefore, an important maintenance goal to ensure the tide gates on these outfalls operate and fully close in dry weather. The mean range of tide is estimated to be 5.2 feet, with mean high water in relation to the North American Vertical Datum of 1988 (NAVD88) at approximately elevation (EL) 2.5' NAVD88.

Stormwater Connections

There are 15 outfalls that contain stormwater connections downstream of the regulator/diversion structure. These connections are generally located between the netting facility and the outfall discharge, although one is located upstream of the netting facility, and one located upstream of

the regulator. For the stormwater connections downstream of the netting facilities a tide gate usually separates them from backing up into the system. The more significant impact is potentially a regulatory one. While CSO outfalls do not overflow for every rainfall event, outfalls with storm drain connections would have a discharge for each wet weather event or during snow melt periods. As each outfall is equipped with a sign stating that if the outfall is overflowing the observer can notify NJDEP at a stated telephone number, this can result in possible instances of reported CSO observations when the CSO Notification System is not indicating such. A reported CSO at these locations may be storm runoff discharging from storm drain connected to the outfall. Table 2-9 can be used to coordinate potential responses to reported CSO discharges due to stormwater connections on the outfall and prevent regulatory issues. While certain regulators may prefer that separate storm sewers have independent outfalls and not be connected to a CSO outfall, land use regulations and levee integrity concerns make the creation of additional outfalls for stormwater runoff very challenging, particularly for locations along the Elizabeth River Flood Control Project where the flood protection elements must be maintained continuously.

Elizabeth River Flood Control Project Drainage Structures

There are 8 CSO outfall discharge outlets that also serve as ERFCP drainage structures outlets. These outfalls convey the flow from both CSO and drainage from ponding areas or storm sewers that are part of the ERFCP. As part of the United States Army Corps of Engineers (ACOE) design for the ERFCP drainage structures, these outfalls have a sluice gate that can be closed to isolate the ERFCP ponding areas from the backwaters that may enter the outfall from a failing tide gate situated at the pipe outlet. If the sluice gate is closed during a wet weather event, excess flow from the upstream regulator would be prevented from discharging and relieving the combined sewer system, creating a potential for flooding of ponding areas and upstream low points. Operation of the drainage structure sluice gates at these coinciding CSO outfall locations should be monitored to prevent closures during wet weather. If a tide gate requires repair at these locations, the repairs should be made as quickly as possible and the sluice gate should be opened prior to a wet weather event.

2.7.2 CSO Regulators and Diversion Structures

The intended purpose of CSO regulators and diversion structures is to route dry weather flows downstream for treatment, typically through a pipe to an interceptor sewer, and to divert excess wet weather flows to an outfall. The City's larger combined sewers have several times the capacity of its interceptor sewers. At each point of combined sewage interception, it is necessary to limit the rate of flow entering the interceptor through the dry weather flow pipe (i.e., underflow or foul sewer pipe). If not limited by the hydraulic capacity of the interconnection, the rate is limited by the capacity of the interceptor or of the Trenton Avenue Pumping Station, which is currently restricted by contract to 36 mgd.

The diversion of combined sewer flows can be accomplished by either mechanical regulators (i.e. the regulator incorporates a mechanism with moving parts) or non-mechanical regulators (i.e., the structure incorporates no mechanism.) Non-mechanical regulators operate based on the overflow elevation in the system. When the wet weather flow surcharges in the system, the non-mechanical regulators use weirs, orifices, vortex valves or pipe invert elevations to control the diversion of wet weather flow.

There are currently 38 CSO regulators and diversion structures in the City sewer system. The location of these structures through the sewer system are shown on Figure 2-3 through Figure 2-5 and Plate A. Detailed schematics indicating the control structure arrangements are given in Appendix B. A comprehensive summary of the control structure characteristics (including the

associated outfall and interceptor; street location; location coordinates; incoming pipe sizes, material, shape, and invert elevations; regulating device size, shape, and elevations; dry weather flow interconnection attributes; overflow control attributes; and outfall pipe size, material, shape and invert elevation at the diversion structure) are presented in Table 2-10.

Each regulator is associated with a CSO outfall and either the Easterly or Westerly Interceptor sewer service areas. Some regulators serve as relief diversion structures and are connected to sewersheds for other regulators. These relief regulators are indicated with light shading and an asterisk in Table 2-10.

The group of interconnected drainage basins tributary to Regulator R005 is likely the most involved where the DWF pipe from R003B connects to R003A, which then in turn connects to the trunk sewer to Regulator R041. Regulators R036A and R036B contribute flow to a separate trunk sewer collecting flow from the R005 sewershed, which then merges with the trunk sewer from R041 before connecting to Regulator R005 and subsequently to the Westerly Interceptor.

Dry weather flow from Regulator R021 is tributary to the Regulator R022 sewershed and similarly, the DWF pipe for Regulator R030 connects downstream to the Regulator R029 sewershed.

Regulators R035, R038A, R038B, and R043 are interconnected, with Regulator R035 having the downstream DWF pipe connection to the Easterly Interceptor. The DWF pipes from Regulators R038A and R038B connect to the trunk sewer within Third Avenue leading to R035, while the R038A and R038B overflow pipes merge prior to discharging through CSO Outfall 038A. Regulator R043 is an emergency relief overflow located on the CSO 035A Outfall.

Regulator R039 is a relief overflow diversion situated on a trunk sewer within Trumbull Street connecting Regulator R034B. Regulator R034B has a DWF pipe connection to the Easterly Interceptor, while the wet weather flow pipe continues as the trunk sewer and the incoming pipe to Regulator R034A, collecting flow from the R034A drainage basin. As such, R034B is an internal diversion to the interceptor and does not have a designated outfall.

The Regulator R042A, B, C and D drainage areas have been partially separated, particularly in the zone surrounding Jefferson and Madison Avenues, from East Grand Street south to Elizabeth Avenue. A large trunk storm sewer was constructed in this drainage district in the mid-1960s, which also serves as the CSO conduit for each regulator in the Outfall 042A drainage system. Regulator R042D provides a relief overflow diversion for the sewershed associated with Regulator R042A, with the DWF pipe continuing through R042D to R042A and then connecting downstream to the Westerly Interceptor. The sewersheds for Regulators R042B and R042C are also interconnected, with the DWF pipe from R042C continuing as a trunk sewer to R042B, from which a dry weather branch sewer extends southerly to the Westerly Interceptor, collecting sanitary flow from lateral connections along the run.

2.7.3 CSO Solids/Floatables Control Facilities

Thirty-five (35) CSO Solids/Floatables Control Facilities were installed throughout the Elizabeth combined sewer system as required by NJPDES permits and the National CSO Policy to reduce solids and floatables entering receiving waters during storm events. These facilities are installed between the regulators and CSO outfalls and only receive wet weather overflow. The control facilities are located in underground vaults which house two or more large net bags designed to trap solids and floatables. In certain locations with lesser flows bar screens were installed. Tide gates are provided downstream of the facilities to restrict tidal back flow that would redistribute solids and floatables back into the sewer system and to facilitate access for maintenance. Some of the facilities also incorporate regulator weirs. These facilities are maintained by the contract

2.7.4 Joint Meeting of Essex and Union Counties Domestic Treatment Works

As NJPDES CSO permittees of a hydraulically connected system, the City of Elizabeth and the Joint Meeting of Essex and Union Counties are working cooperatively to ensure that the Long Term Control Plan (LTCP) activities are developed consistently. The City and JMEUC have been coordinating closely on the preparation of System Characterization Reports for their respective facilities and are jointly certifying each characterization report. Furthermore, the City and JMEUC are working cooperatively to develop, finalize, and submit a single, comprehensive LTCP per the CSO Permit provisions based on the integrated system characterization.

The discussion below presents the basic characteristics of the JMEUC system. The reader should refer to the JMEUC System Characterization Report (June 2018) for specific information on the records review, system monitoring, and modeling results associated with the comprehensive characterization of the JMEUC system.

JMEUC Trunk Sewers

The JMEUC owns, operates, and maintains a gravity trunk sewer system that conveys wastewater from 17 municipalities in Essex and Union Counties to its wastewater treatment plant located on South First Street in Elizabeth, NJ. In most locations, the system consists of 2 parallel trunk sewers, the Original Trunk and the Supplemental Trunk sewers.

Original Trunk

The 42" diameter brick Original Trunk was constructed around 1900 and trunk extends approximately 2.6 miles through the City along North Avenue, Elmora Avenue, and Bayway, from the municipal boundary with Union Township to its present confluence with the Supplementary Trunk at Bayway and Pulaski Street.

Supplemental Trunk

The Supplemental Trunk was completed circa 1932 and extends about 4 miles through the City, running southwesterly within Monmouth Road from the Union Township border, then along the municipal boundary through Standish Street, Acme Street, Watson Avenue, Richford Terrace, Allen Street, and Myrtle Street to Pulaski Street, where the Original Trunk connects to it. Along this route, the Supplemental Trunk is reported as being constructed of concrete and ranging from 72" to 81" diameter. The Supplemental Trunk continues from Pulaski Street to the WWTP as two (2) 5'-8" wide by 5'-7" high concrete box culverts.

A branch of the Supplemental Trunk, referenced herein as the Roselle Park Supplemental Trunk Branch sewer, intercepts and conveys flows from Roselle Park, running along Galloping Hill Road and then Westfield Avenue within the City to the connection with the Supplemental Trunk at Colonia Road and Monmouth Road.

City Branch Connections

When the JMEUC trunk sewers were constructed, their vertical alignment intersected many pre-existing local City branch sewers. These branch sewers, which mostly serve areas west of Elmora Avenue along the City's western boundary, were therefore connected directly to the JMEUC trunks. About 14.7 miles of City branch sewers, including about 580 manholes and 240 catch basins, with a total tributary area of approximately 454 acres, are associated with these direct connections to the JMEUC trunk sewers in Elizabeth.

There are an estimated 27 City combined and sanitary sewer connections that discharge directly into the JMEUC trunks, each with a tributary sewer length ranging from 0.04 to 2.0 miles. Twenty (20) connections discharge to the Original Trunk and 7 connections discharge to the Supplemental Trunk. The longest of these branch sewers is approximately 2.0 miles long and connects to the Original Trunk at Park Avenue, with tributary sanitary flow from Roselle Park at its upstream end. Furthermore, only 2 branches connected to the Supplementary Trunk are longer than 500 feet: (1) the Galloping Hill Road branch that enters the Roselle Park Supplemental Trunk Branch at the Roselle Park border, and (2) the Verona Avenue - Gebhardt Avenue branch that enters at the Union Township boundary.

JMEUC Wastewater Treatment Plant

The Joint Meeting Wastewater Treatment Plant is bound by the Elizabeth River to the northeast, the Conrail railroad and the New Jersey Turnpike to the northwest, the relocated Bayway roadway to the southwest, and South First Street to the southwest. A portion of the plant extends to the south side of South First Street.

The facility utilizes an activated sludge secondary treatment process with surface aerators and has a permitted average daily flow capacity of 85 mgd. At the JMEUC plant, wastewater receives preliminary treatment through mechanical coarse screens, mechanical fine screens, and gravity grit chambers. Wastewater then flows to four rectangular primary clarifiers. The primary clarifier effluent is conveyed to four aeration tanks by five low lift pumps. The aeration tanks are equipped with mechanical aerators. From the aeration tanks, the mixed liquor flows to four circular secondary clarifiers. The secondary effluent is then disinfected using sodium hypochlorite, and then dechlorinated with sodium bisulfite. The treated wastewater is then discharged to the Arthur Kill through two outfall conduits.

The primary sludge is screened to remove grit and other large solids. The waste activated sludge (WAS) is pumped to four thickener tanks; the partially thickened WAS is thickened further using gravity belt thickeners. The screened primary sludge and thickened WAS is pumped to four primary digesters, where anaerobic digestion is used to stabilize the sludge.

From the digesters the sludge is pumped to two sludge storage tanks and then on to the dewatering facility where it is dewatered using three centrifuges. After dewatering, the sludge is lime stabilized and loaded into trucks for land application.

2.7.5 City Interceptors and Trunk Sewers

The City's sewer system tributary to the Trenton Avenue Pumping Station, its main sewage pumping station, is served by Easterly and Westerly Interceptors. Each interceptor enters the Trenton Avenue PS through a 60" diameter reinforced concrete pipe (RCP). The City interceptors intercept various local trunk and branch sewers. Table 2-12 summarizes certain data for the City interceptors, interceptor branches, and major trunk sewers, while Figure 2-3 through Figure 2-5 depict their locations and arrangement within the system.

Table 2-12: City Interceptors and Major Trunk Sewers

Interceptor Name	Sewer Length	Downstream Pipe Size	Downstream Pipe Material	Total Tributary System Length
Branch Interceptor Name				
Trunk Sewer Name	(miles)	(inches)	(-)	(miles)
Easterly Interceptor	4.30	60	RCP	58.7
Division Street Branch	0.27	24	RCP	
East Side Industrial Branch	0.56	18	PCCP	1.43
Bayway Branch	0.93	30	VCP	1.56
Alina St / Van Buren St / North Ave Trunk	1.50	48	RCP	14.1
Fairmount Ave Trunk	0.40	48	RCP	5.56
Trumbull St / Sixth St Trunk	1.48	48 x 72	Brick Egg	12.7
Magnolia Ave Trunk	0.26	30 x 45	Brick Egg	3.00

Front St Trunk	1.32	44 x 63	Brick Egg	3.41
Third Ave Trunk	0.57	48	RCP	5.09
Bayway Trunk	0.26	72	Brick	1.07
Westerly Interceptor	2.30	60	RCP	78.9
W Jersey St / W Grand St Branch	0.16	12	VCP	1.04
Rahway Ave / Cherry St Branch	0.25	12	VCP	3.68
Pearl St / Burnet St Branch	0.50	12	VCP	1.97
South St Branch	0.08	15	VCP	6.76
Palmer St / John St Branch	0.26	20	VCP	4.54
Westfield Ave / Park Ave Trunk	1.23	54	CCFRPM	8.00
Grove St / Pennington St / Elmora Ave Trunk	0.86	48 x 72	Brick	4.97
Magie Ave Trunk	0.26	18	VCP	0.392
Orchard St / Morris Ave Trunk	0.78	72	RCP	23.4
Union Ave / Newark Ave Trunk	1.24	48 x 72	Brick Egg	15.4
Bridge St / Jefferson Ave Trunk	0.79	42 x 63	Brick Egg	5.22
Reid St / East Grand St Trunk	0.86	48 x 72	Brick Egg	6.64
John St / Niles St Trunk	0.52	36 x 54	Brick Egg	4.28
Summer St / South Elmora Ave Trunk	0.68	60	RCP	7.34

Abbreviations: Brick Egg = Egg-shaped brick masonry sewer; CCFRPM = centrifugally cast fiberglass reinforced polymer mortar; PCCP = pre-stressed concrete cylinder pipe; RCP = reinforced concrete pipe; VCP = vitrified clay pipe.

Easterly Interceptor

The Easterly Interceptor consists of approximately 23,400 linear feet of RCP ranging in size from 33" to 60" diameter constructed in 1958. It starts in the northern portion of the City at Regulator R001, located in the grassed border adjacent to the NJ Route 81 North exit ramp connector for US Route 1-9 North and Newark Liberty International Airport. The interceptor then flows southeasterly along NJ Route 81 and Dowd Avenue, across the New Jersey Turnpike and Conrail lines, and through easements to Trumbull Street at Second Street and to Front Street at Port Avenue. The interceptor continues southwest along Front Street, northerly along Elizabeth Avenue, and southwest again along South First Street. The interceptor then heads northwesterly along the Elizabeth River to the Trenton Avenue Pumping Station. The 60" RCP interceptor reduces to twin 36" ductile iron pipes where it crosses beneath the Elizabeth River near the end of South Second Street.

The additional 1,400-foot long Division Street branch of Easterly Interceptor is comprised of 24" RCP and runs from Regulator R002 at Fairmount Avenue to the interceptor at Dowd Avenue. In the late 1960s, the Bayway branch of the Easterly Interceptor was constructed, running northeasterly from Regulator R037A along Bayway, South Front Street, Clifton Street, and through easements to its interceptor connection adjacent to the Elizabeth River, east of the New Jersey Turnpike and Conrail lines. The Bayway branch is about 4,800 feet long, 24" and 30" diameter VCP. A 2,900-foot long, 18" diameter pre-stressed concrete cylinder pipe (PCCP), referred to on the record plans as the East Side Industrial Waste Sewer, conveys flows from Regulator R034A through easements south of Slater Drive to the interceptor at Front Street and Port Avenue.

The Easterly Interceptor receives flows from a sewage service area of 3,690 acres, including 1,570 acres of combined sewers associated with Regulators R001, R002, R029, R030, R031, R032, R034A and B, R035, R037A and B, R038A and B, and R039. It also receives flow from the largest separate sewer areas of the City associated with the Kapkowski Road Pumping Station and along Dowd Avenue. The system tributary to the Easterly Interceptor includes approximately 58.7 miles of sewer main, 2,350 manholes, and 1,070 storm inlets and catch basins.

Westerly Interceptor

The Westerly Interceptor serves the northern, central, and western parts of the City, with the main branch beginning at the Union Street, Morris Avenue, and Westfield Avenue intersection, connecting to Regulator R005. The Westerly Interceptor flows southerly along Union Street to West Jersey Street, easterly across the Amtrak railroad lines to Elizabethtown Plaza, and then southerly to Rahway Avenue. The interceptor continues easterly along Rahway Avenue and Elizabeth Avenue to Bridge Street, and then runs southerly across the Elizabeth River to Pearl Street. It then flows southerly along South Pearl Street, through Grove Street to Clarkson Avenue. From Clarkson Avenue at Britton Street, the Westerly Interceptor is mostly routed along the western bank of the Elizabeth River to the Trenton Avenue Pumping Station.

The Westerly Interceptor main branch is approximately 11,900 feet long, with the section from Regulator R005 to Clarkson Avenue at Britton Street being of brick masonry construction ranging from 28" to 40" in diameter. The siphon across the river at Bridge Street is associated with this section, consisting of 2 ductile iron pipe (DIP) barrels, one 16" and the other 24" diameter, each approximately 130 feet long. The section from Clarkson Avenue at Britton Street to the Trenton Avenue Pumping Station is comprised of 48" and 60" diameter RCP installed in the late 1950s, extending the interceptor to the then constructed Trenton Avenue PS. In the late 1980s, the brick masonry interceptor pipe was lined with cured-in-place-pipe (CIPP) to reduce

friction and improve conveyance capacity. The lining reduced the internal diameter of the original brick sewers by about 1.5”.

Several large trunk sewers extend from the interceptor through upstream sewersheds and are described further below. Moreover, long branches connect the Westerly Interceptor to various upstream regulators. These branches include:

- The West Jersey Street / West Grand Street branch, which is approximately 900 feet long, predominantly of 12” diameter VCP and polyvinyl chloride (PVC) pipe, and incorporates the West Grand Street siphon. The branch receives flow from Regulator R008 and conveys it to the Westerly Interceptor on east side of the Elizabeth River at West Jersey Street and Union Street.
- The Rahway Avenue / Cherry Street branch, which is approximately 1,100 feet long, predominantly of 12” diameter VCP, and includes the Rahway Avenue siphon. It receives flows from Regulators R010, R011, and R013 and conveys it to the Westerly Interceptor on the east side of the river at Rahway Avenue and Elizabethtown Plaza. A relief interconnection to the Pearl Street / Burnet Street branch exists to relieve known hydraulic issues with the Rahway Avenue Siphon and downstream connections.
- The Pearl Street / Burnet Street branch, which is approximately 2,600 feet long, predominantly of 12” diameter VCP. It receives flows from Regulator R016 and conveys it to the Westerly Interceptor on the west side of the Elizabeth River at Pearl Street and Bridge Street. This branch can also convey flow from a relief interconnection from the Rahway Avenue / Cherry Street branch.
- The South Street branch, which is approximately 600 feet long, predominantly of 12” diameter VCP and polyvinyl chloride (PVC) pipe, and incorporates the South Street siphon. The branch receives flow from Regulator R022 and conveys it to the Westerly Interceptor on west side of the Elizabeth River at South Pearl Street and South Street.
- The Palmer Street / John Street branch, which is approximately 1,600 feet long, predominantly of 15” and 20” diameter VCP pipe, and includes the Palmer Street siphon. The branch receives flow from Regulator R026 and conveys it to the Westerly Interceptor on the west side of the Elizabeth River at Clarkson Avenue south of Fillmore Street.

The Westerly Interceptor receives flows from a sewer service area of 2,140 acres, including 1,890 acres of combined sewer system areas associated with Regulators R003A, R003B, R005, R008, R010, R012A, R011, R013, R014, R016, R021, R022, R026, R027/028, R027/028, R036A, R040, R041, and R042A, B, C and D. Approximately 78.9 miles of sewer main, 3,330 manholes, and 1,270 storm inlets and catch basins are estimated to contribute flow to the Westerly Interceptor.

City Trunk Sewers

Seventeen (17) trunk sewers with a total length of about 13.3 miles are listed in Table 2-12 for the City’s combined sewer system. Each trunk sewer receives and conveys flows from a relatively large area and has substantial branch sewer connections. Eight (8) trunk sewers contribute flow to the Easterly Interceptor and 9 trunk sewers flow to the Westerly Interceptor. Many trunk sewers are egg-shaped or circular brick sewers, ranging in size from 30” wide by 45” high to 60” wide by 90” high.

As shown on Figure 2-3 through Figure 2-5, regulator / diversion structures R001, R002, R003A and B, R005, R022, R027/028, R029, R030, R031, R032, R034B, R035, R036A and B, R037A and B, R038A, R039, R041, and R042A, B, C and D are situated along these major trunk sewers. Some regulators, including R003A and B, R036A and B, R034B, R039, R041, and R042B and C, are positioned a good distance upstream of a corresponding interceptor or

branch interceptor, with dry weather flows continuing to downstream sewersheds and excess wet weather flows diverted to CSO outfalls.

The Orchard Street / Morris Avenue trunk runs upstream of Regulator R005 to Regulator R003A and is comprised of about 800 linear feet of 72" diameter brick masonry and 2,500 feet of gunite coated 60" wide by 90" high brick sewer. Upstream of Regulator R003A, the Westfield Avenue / Park Avenue trunk extends approximate 2,700 feet along Westfield Avenue, Elmora Avenue, and Park Avenue to Springfield Road and is comprised of centrifugally cast fiberglass reinforced polymer mortar (CCFRPM) pipe ranging from 48" to 54" diameter. Dry weather flows from Regulator R003A continue through the Orchard Street / Morris Avenue trunk, which also collects branch sewer flows within CSO Drainage Basin 041 before reaching Regulator R041. The Union Avenue / Newark Avenue trunk receives branch sewer flows from Drainage Basin 036 before reaching Regulator R036, then continues on to collect branch sewer flows from Drainage Basin 005. The Orchard Street / Morris Avenue trunk and the Union Avenue / Newark Avenue trunk then merge before connecting to Regulator R005.

2.7.6 Sewer Pipe Inventories and Distributions

Based on current GIS information, the Elizabeth sewer system has about 1,125,000 feet, or 213 miles, of pipe associated with it (including sewer mains, outfalls, interceptors, and force mains, but not building sewers and laterals). Approximately 78% of the Elizabeth sewer system is comprised of combined sewers by length, while 18% is classified as separate storm sewers and 4% is classified as separate sanitary sewer.

Table 2-13 provides a tabulation of the total length of sewers within the system by sewer system type and pipe material. As indicated in the table, about 57% of the sewers within the overall sewer system is constructed of VCP. The majority of the combined sewer system is constructed of VCP at 67%, RCP at 14%, and brick masonry sewer at 9%, which is a reflection of the age of the system. Other pipe materials recorded for the combined sewers include PVC, ductile iron, cast iron, pre-stressed concrete cylinder pipe, unreinforced concrete, CCFRPM, and lesser amounts of asbestos cement, high density polyethylene, and corrugated metal pipe. Pipe material information is not listed for about 3.5% of the combined sewer asset class.

Separate sanitary sewers are predominantly comprised of VCP, DIP, RCP and PVC pipes. Separate storm sewers are predominantly comprised of RCP, VCP, HDPE, and CIP; however, about 19% of the inventoried separate storm sewers are of unknown pipe material.

Table 2-14 lists the distribution of sewer lengths (including sewer mains, outfalls, interceptors, and force mains, but not building sewers and laterals) by pipe size range and sewer system type, based on the pipe sizes available in the current GIS database. The combined sewers, in general, range in size from 4 inches to more than 13.5 feet in height, with nearly 64% between 8" and 16". About 75% of the combined sewer are reported as less than 24" diameter (or minimum internal dimension) and over 10% is greater than 42".

In many combined sewer systems, VCP ranging from 6" to 24" diameter is typical, and larger pipe is constructed of brick or RCP. Brick combined sewers are either circular ranging in size between 15" and 84" diameter or egg-shaped ranging in size between 16" wide by 24" high and 60" wide by 90" high, inside dimensions.

Table 2-13: Tabulation of Sewer Lengths by Pipe Material and Sewer System Type

Pipe Material	Combined			Separate Sanitary		
	Length (feet)	Length (miles)	Percent	Length (feet)	Length (miles)	Percent
VCP	589,300	111.6	67.39%	26,600	5.0	53.20%

Includes gravity sewers, force mains, interceptors, and CSO outfall.

2.7.7 Pumping Stations

There are 3 pumping stations within the City that handle dry weather sanitary sewage: the Trenton Avenue Pumping Station (TAPS) located at Trenton Avenue and the Elizabeth River; the Kapkowski Road Pumping Station located at the intersection of Kapkowski Road and North Avenue East; and the West Jersey Street Pumping Station located on West Jersey Street between Cherry Street and Price Street. The Kapkowski Road and West Jersey Street pumping stations receive flow from separate sewer systems, but discharge into the combined sewer system for treatment. As previously noted, TAPS is the main pumping station situated at the downstream point of the sewer system and conveys the majority of flows from the City to the JMEUC WWTP, including the tributary flows from the Kapkowski Road and West Jersey Street pumping stations. These stations are further described below.

Additionally, there are 6 stormwater pumping stations (SWPS) within the City: Arch Stormwater Pumping Station, Verona-Gebhardt Stormwater Pumping Station, and four stations constructed by the Army Corps of Engineers as part of the Elizabeth River Flood Control Project. Due to connections with CSO outfalls, certain stormwater pumping stations can influence the combined sewer system hydraulics, as noted below. These stations are therefore incorporated in the characterization and the collection system model.

Trenton Avenue Pumping Station

Trenton Avenue Pumping Station (Trenton Avenue PS or TAPS) is located on the west bank of the Elizabeth River on the south side of Trenton Avenue. The Trenton Avenue PS replaced an earlier pumping station in Clarkson Avenue at Britton Street in 1958, when the Easterly Interceptor and downstream extension of the Westerly Interceptor were constructed. Sanitary sewage from all areas served by the City's sewer system, except those lines connected directly to the JMEUC Original and Supplemental Trunk sewers, is conveyed to TAPS. From the Trenton Avenue PS, sewage is pumped into the JMEUC influent sewer approximately 1,500 feet from the JMEUC WWTP.

Dry weather flows are conveyed to JMEUC WWTP by the TAPS. The ultimate pumping capacity (i.e., all pumps running) of the TAPS is 55 mgd, however, by agreement with JMEUC, the maximum peak flow that can be discharged to JMEUC by the TAPS is 36 mgd and average daily flow is limited to 18 mgd. Rainfall events producing wet weather flows in the interceptors that exceed 36 mgd are throttled by influent gates at the entrance to the pumping station resulting in excess combined wastewater being discharged into the receiving waters as a combined sewer overflow.

The Trenton Avenue Pumping Station is comprised of two influent channels with an interconnecting sluice gate, two influent sluice gates, two mechanical bar screens, and two wet wells with an interconnecting sluice gate. This provides an independent pumping train for each interceptor if required and the flexibility to divert flow to one wet well side while working on the other. Pumps are located in a dry well, shaft driven by motors on the first floor of the pumping station. The easterly train has three pumps (Nos. 1, 2 and 3) and the westerly train has two pumps (Nos. 4 and 5). All pumps discharge into a common discharge header within the station and flow passes through a flow meter prior to exiting the station. The 48" diameter PCCP force main, approximately 930 feet in length, runs west to Trenton Avenue through the pumping station property, then south in Trenton Avenue, and connects into the JMEUC WWTP influent sewer approximately 200 linear feet south of Clifton Street.

Metered flow is totalized and the rate is recorded on 24-hour circular charts. The totalizer is read and recorded each day at about 7 AM when the chart is changed. Daily total flow is determined by the difference in totalizer readings. No electronic flow records are available.

TAPS was constructed in 1954 and upgraded in 1983. The mechanical bar screens were replaced in 2003 with vertical two rope bar screens, the screening grinders were rebuilt, new windows and doors were installed in the screening and wet well area and the area was cleaned and repainted. In 2015, improvements were made to harden the facility against catastrophic flooding as occurred during Hurricane Sandy. Equipment at the pump station is regularly replaced as the items reach the end of their service life. Recent and planned replacements include the effluent flow meter, the variable speed drives and controls, and the discharge check valves.

Pump nameplate data is presented in Table 2-15.

Table 2-15: Trenton Avenue Pumping Station, Pump Nameplate Data

Pump No.	1	2	3	4	5

Reported Flow *	10 mgd	15 mgd	13 mgd	13 mgd	13 mgd

* As reported by the sewer system operator.

Kapkowski Road Pumping Station

The Kapkowski Road Pumping Station is located at the intersection of North Avenue and Kapkowski Road and serves the area bounded by the New Jersey Turnpike on the west, the Elizabeth Channel on the north, Newark Bay on the east and the Conrail railroad tracks east of Trumbull Street on the south. The pumping station collects sanitary sewage from this area and pumps the sewage 5,350 feet in a 16" DIP force main to the Easterly Interceptor where it crosses Veterans Memorial Drive. As the Easterly Interceptor also receives combined sewage from upstream and downstream sewersheds during wet weather, flow from the Kapkowski Road Pumping Station separate sewer tributary area may affect or be affected by the combined sewer system. Therefore, information on the Kapkowski Road PS equipment and operating elevations have been included in the current CSS model.

The Kapkowski Road Pumping Station was constructed in 1993 and is comprised of the following components:

- Influent channel with a muffin monster grinder (comminutor).
- Influent channel slide plates.
- Influent raw sewage wet well.
- Dry well with three non-clog sewage pumps;
 - Extended shaft driven by 20 horsepower electric motors located on the first floor.
 - Pumps No. 1 and 2 are equipped with variable frequency drives.
 - Pump No. 3 is fixed speed and the lag pump.
 - There are provisions available for a future Pump No. 4, if required.

The station currently pumps in the range of 53,000 gallons per day (gpd) average daily flow. In dry weather, the station typically requires only one pump operating. Flow charts reveal that there is minimal increase in influent flow to the station during wet weather events, suggesting a tight tributary collection system.

West Jersey Street Pumping Station

The West Jersey Street Pumping Station services a very small area of the City that includes those properties on both sides of West Jersey Street between Cherry Street and the Elizabeth River, for a distance of about 300 feet. The station was constructed by the ACOE for the Elizabeth River Flood Control Project to replace an existing siphon that interfered with the

concrete channel constructed to route the Elizabeth River through the midtown area. The duplex submersible pumping station discharges through a 4" ductile iron force main suspended beneath the West Jersey Street bridge to a gravity sewer manhole on the opposite side approximately 100' from the pumping station. Pumps are reported to be 5.4 horsepower Wilo-EMU non-clog submersible, Model FA 101, rated for 591 gpm at 21.8 feet of total dynamic head.

Arch Stormwater Pumping Station

The Arch Stormwater Pumping Station, located on East Broad Street between North Broad and Walnut Streets, was constructed circa 1972 and collects stormwater from the underpass of the Amtrak Northeast Corridor mainline and a 2nd inactive and abandoned elevated railroad, at the intersections of Broad Street, East Broad Street, North Broad Street, and Morris Avenue. In heavy rains, this low area can flood, impacting traffic and business activities in this vital City commuter, institutional, and mercantile area.

The Arch SWPS has an approximate capacity of 134 cubic feet per second (cfs), or 86.6 mgd, and has a total of 4 low lift high capacity pumps that lift stormwater about 20 feet to an effluent channel within the station that transitions to 54" diameter RCP gravity sewer. There are 2 variable speed pumps (rated at 22.3 cfs each) and 2 constant speed pumps (rated at 44.6 cfs each.) Influent is screened by a 16-foot wide vertical mechanical bar screen that discharges screenings into the effluent channel. The station is also equipped with a natural gas emergency standby power generator.

The Arch SWPS relates to the combined sewer system in that its 54" diameter discharge conduit connects to CSO Outfall 042A at Jefferson Avenue and East Grand Street, where the outfall pipe is 72" diameter RCP. This Outfall receives excess flows diverted from Regulator R042C upstream and R042A, R042B, and R042D downstream of the pump station discharge connection. As such, flows from the Arch SWPS can influence the diversion from these CSO control structures and the CSO Outfall 042A discharge. This pump station and its operating characteristics have been included in the current CSS model.

Army Corps of Engineers Stormwater Pumping Stations

Four (4) stormwater pumping stations were constructed by the ACOE as part of the Elizabeth River Flood Control Project in the late 1970s and early 1980s. These pumping stations are designed to drain major ponding areas situated on the protected side of the levee when gravity flow drainage through the levee is not sufficient due to tide elevations. The 4 stations are located adjacent to the Elizabeth River at South Street, Mattano Park, South Second Street, and South First Street. The South Second Street SWPS was recently rehabilitated and returned to service after many years of being off-line. The South First Street SWPS serves only the JMEUC property and is currently off-line. JMEUC has assumed operation and maintenance of this station and has plans to rehabilitate and upgrade it. Generally, the stations function the same as the Arch SWPS but discharge directly to the Elizabeth River.

The Mattano Park and South First Street SWPS do not have any direct connection to the combined sewer system. Regarding the South Street SWPS, CSO Outfall 022A is connected to the station's intake chamber and the station's outlet structure also serves as the outlet for CSO Outfall 022A. As such, the South Street SWPS can facilitate the discharge of combined flows from CSO 022A at high stages in the Elizabeth River, preventing backwater effects at Regulator R022. Information on the pump curves and operating elevations for this station are included in the current CSS model.

The South Second Street SWPS is located on the left bank (facing downstream) of the Elizabeth River and was constructed to dispose of local storm runoff that collects in a ponding area situated behind the levee embankment between South First and South Second Streets. The connection with the combined sewer system is with Emergency Relief Outfall 043A, which when active, flows through a drainage channel that is connected to the South Second SWPS intake chamber. Given the limited elevation difference between the intake chamber inlets and Outfall 043A overflow weir, high water levels in the intake chamber will influence the performance of Emergency Relief Outfall 043A. Information on the pump curves and operating elevations for this station are included in the current CSS model.

Verona-Gebhardt Stormwater Pumping Station

The Verona-Gebhardt Stormwater Pumping Station was completed in 2011 to mitigate localized flooding in a residential neighborhood abutting the Township of Union and Kean University. In addition to the pumping station, the project involved separating a previous combined sewer network in this area. As such, the station does not have a direct connection to the combined sewer system and following is provided for informational purposes only.

The Verona-Gebhardt SWPS is comprised of a large, below-grade, precast concrete vault structure with a precast concrete above grade control building located on Kean University property. Four (4) submersible ABS pumps, with a total capacity of 80 cfs, discharge to Trotters Brook, a tributary of the Elizabeth River via a flow control structure and swale with outlet protection. The drainage area to the station is approximately 53 acres in both the City of Elizabeth and the Township of Union to the west of Monmouth Road and north of Magie Avenue. Stormwater storage is also provided with approximately 1,300 linear feet of 6.5' wide by 7' high box culvert in Verona Avenue, with a 48" diameter RCP connection to the pumping station.

2.7.8 Siphons

The City sewer system contains 8 siphons. Seven siphons are in the Westerly Interceptor drainage basin and 1 siphon is in the Easterly Interceptor drainage basin. Six siphons cross the Elizabeth River, 1 siphon was constructed to facilitate the installation of a 166" wide by 106" high horizontal elliptical reinforced concrete pipe (HERCP) CSO outlet and storm sewer on Union Avenue, and 1 siphon was constructed to facilitate the installation of a 98" wide by 63" high storm sewer on Division Street. The siphons are located at:

- Union Avenue at Oakwood Place
- Morris Avenue at the Elizabeth River
- West Grand Street at Price Street
- Rahway Avenue at the Elizabeth River
- Bridge Street at the Elizabeth River
- South Street at the Elizabeth River
- Palmer Street at the Elizabeth River
- Dowd Avenue at Division Street

The Union Avenue siphon was constructed in 1971 to convey flows from regulator basin R005A beneath the 166" by 106" HERCP CSO outlet and storm sewer in Union Avenue. The double barrel siphon is comprised of 12" and 24" diameter ductile iron pipe and requires regular maintenance to clear obstructions, remove trapped floatables, and avoid backups in the tributary sewers.

The siphons at Morris Avenue, West Grand Street, Rahway Avenue, Bridge Street, and South Street are all similar U.S. Army Corps of Engineer (ACOE) designs. At these locations, the river is contained within a rectangular concrete channel constructed in conjunction with the levee system as part of the Elizabeth River Flood Control Project in the late 1970s through early 1980s.

The Morris Avenue siphon is a triple barrel (8" and two 14" diameter) siphon that conveys the Westerly Interceptor in Morris Avenue beneath the Elizabeth River. Flows from the sewersheds for Regulators R003A, R003B and R041 are tributary to this siphon. Regulator R041 is located immediately upstream of the siphon.

The West Grand Street siphon is a double barrel (6" and 12" diameter) siphon that conveys flow from Drainage Basin 008 west of the Elizabeth River to the Westerly Interceptor at Union Street. Issues with clogging and restrictions in both siphon pipes have been reported in the past.

The Rahway Avenue siphon is a double barrel (6" and 10" diameter) siphon that conveys flows from Drainage Basins 010 and 013 through the Rahway Avenue /Cherry Street branch interceptor to the Westerly Interceptor at the intersection of Elizabethtown Plaza and Rahway Avenue, on the east side of the river. Depending on the hydraulic conditions in the Rahway Avenue branch interceptor, flow through this siphon may come from the opposite direction, back towards a relief interconnection to the Pearl Street / Burnet Street branch interceptor.

The Bridge Street siphon is a double barrel (16" and 24" diameter) siphon that conveys the Westerly Interceptor beneath the Elizabeth River. This siphon and the associated interceptor connection tended to accumulate significant sediment in the past, substantially reducing its conveyance capacity. In 2009, the Bridge Street siphon was thoroughly cleaned, which re-established flow capacity and the siphon is regularly inspected.

The South Street siphon is a double barrel (two 8" diameter) siphon that conveys flow from Drainage Basin 022 on the east side of the Elizabeth River to the Westerly Interceptor in Pearl Street on the west side.

The Palmer Street (paper street) siphon is a double barrel (two 10" diameter) siphon that conveys flow from Drainage basin 026 on the east side of the Elizabeth River to the Westerly Interceptor in Clarkson Avenue on the west side of the Elizabeth River. At this location, the river is confined by the levee system and stormwater ponding areas are located between the levees and adjacent streets. The siphon outlet manhole located at the toe of slope of the levee embankment has made access for maintenance difficult.

The Dowd Avenue siphon was constructed circa 1982 to convey the Easterly Interceptor beneath a 98" by 63" HERCP storm sewer in Division Street as it crosses Dowd Avenue. Flows from Drainage Basin 001 are tributary to this siphon, while flow from regulator R002 discharges to the Easterly Interceptor a short distance downstream of the siphon. The siphon consists of 2 pipe barrels: a 10" diameter cast-iron pipe primary barrel (situated at the incoming sewer invert elevation) and a 24" diameter cast-iron pipe secondary barrel (situated at a higher elevation).

2.8 Significant Indirect Users

The NJPDES CSO Permit requires that impacts from significant indirect users (SIUs) contributing to the CSOs are minimized. Based on the loading and toxicity of SIU contributions, each SIU is required to incorporate a level of pretreatment prior to discharge to the sewer system. JMEUC monitors SIUs for compliance with pretreatment requirements.

Significant indirect users located in the City of Elizabeth are shown on Figure 2-3 through Figure 2-5 and listed in Table 2-16. There are 17 SIU facilities in Elizabeth, with rated flows varying from less than 0.001 mgd to 0.34 mgd and 15 locations having pre-treatment requirements. Eight (8) SIUs do not contribute flow to a sewer tributary to a CSO regulator / diversion structure. Three (3) SIUs are located within CSO Basin 039 and 2 SIUs are within CSO Basin 022. Given the location, flows, and pretreatment provided, the SIUs appear to have no significant impact on CSOs.

Table 2-16: Significant Indirect Users

ID	Name	CSO Basin	Street Address	Flow (mgd)	SIC Code	Pre-treatment
1	814 Americas, Inc. (Div. of Patrick Cudahy Inc.)	022	812-814 Second Avenue	0.01	Meat Processing - 2013	Yes

2.9 CSO Drainage Basin Descriptions

Further information on each of the CSO drainage basins is provided in this subsection. The CSO basins have been divided by the City interceptor sewer to which the basin is tributary. For each CSO basin, a general description is given, along with information on pipe materials and sizes, regulator, solids/floatables controls, outfall, land use, significant indirect users, and

interconnectivity with other basins. Enlarged maps of the drainage basins are included herein, grouped by interceptor sewer and proximity. Where an interconnection between basins exist, the location of the interconnection is indicated on the figure. The figure numbers and corresponding CSO drainage basins are as follows:

- Easterly Interceptor
 - Figure 2-9: CSO Basins 001 & 002
 - Figure 2-10: CSO Basins 029, 030, 031 & 032
 - Figure 2-11: CSO Basins 034 & 039
 - Figure 2-12: CSO Basins 035 (043), 037 & 038
- Westerly Interceptor
 - Figure 2-13: CSO Basins 003 & 041
 - Figure 2-14: CSO Basins 005 & 036
 - Figure 2-15: CSO Basins 008, 010, 011, 012, 013, 014 & 016
 - Figure 2-16: CSO Basins 021, 022 & 026
 - Figure 2-17: CSO Basins 027/028 & 040
 - Figure 2-18: CSO Basin 042

2.9.1 Easterly Interceptor Drainage Basins

CSO Drainage Basin 001

General description: CSO Basin 001 is shown on Figure 2-9 and covers approximately 440 acres. It consists of the area surrounding the Alina Street / Van Buren Avenue / North Avenue trunk sewer in the northern portion of the City. While surrounded by CSO Basin 002, properties on the east side of US Route 1-9 from Bond Street to Woodruff Land flow to Regulator R001. The Fanny Street location and the adjacent streets have had sewer separation projects that have partially separated storm runoff from the area and discharge it to the Peripheral Ditch. The northern areas near Cross Avenue also have separate storm sewers that drain to Lake Weequahic located in the City of Newark.

Significant Indirect Users: There are no SIUs in this drainage basin.

Regulator: The Alina Street / Van Buren Avenue / North Avenue trunk is regulated at Regulator R001, which is the start of the Easterly Interceptor and has an overflow outfall to the Peripheral Ditch. Flow from the trunk sewer enters the regulator, with dry weather flow continuing to the Eastern Interceptor which runs along Dowd Avenue. Overflow control during wet weather events is provided by a 48" wide by 36" high opening with an invert elevation of EL 1.59' NAVD88 and a 48" diameter overflow pipe.

Outfall and Solids/Floatables Control Facilities: The outfall pipe runs about 200 feet before entering the netting chamber. This netting chamber has a single tier netting system with 3 nets. Flow passes through the nets to remove solids and floatables, and then continues into the outfall pipe.

From the netting chamber, the outfall runs about 50 feet to an outlet discharging into drainage ditch leading to the Peripheral Ditch. The discharge point is not normally influenced by tides, but tide gates are provided at the regulator and netting chamber. Tidal influence at the outfall is prevented by a tide gate structure and pump station installed at the Peripheral Ditch downstream end which isolates it from the tides of the Newark Bay. The ditch is also located in an area that is inaccessible to the public. The entirety of the ditch is located within the fenced

property of Newark Liberty International Airport, which is owned by the Port Authority. There is one storm sewer connection to the outfall downstream of Regulator R001 that conveys storm water from the separate storm drainage system from US Route 1-9.

Diversions to and from Other Basins: There are no interconnections to adjacent basins.

CSO Drainage Basin 002

General description: CSO Basin 002 is shown on Figure 2-9 and covers 223 acres. It consists of the area around the Fairmount Avenue trunk sewer. Properties on the west side of US Route 1-9 from Bond Street to Woodruff Lane and along Fairmount Avenue west of US Route 1-9 adjoin Basin 001, but are tributary to Regulator R002. The Division Street area has had sewer separation projects that have partially separated storm runoff from the area. The resulting stormwater is piped under NJ Route 81 to a discharge point along the Peripheral Ditch. Although a large area has separate storm sewers, storm drain inlets in the upstream reaches maintain the trunks as combined sewers.

Significant Indirect Users: Wakefern Food Corporation, a food warehousing and distribution facility with a permitted flow of 0.016 mgd and a pretreatment program, is located in this CSO basin.

Regulator: The Fairmount Avenue trunk ends at Regulator R002, which discharges dry weather flows to the Division Street branch interceptor and then to the Easterly Interceptor at Dowd Avenue. Overflow control during wet weather events is provided by a 48" wide by 36" high opening with an invert elevation of EL 4.02' NAVD88 and a 48" diameter overflow pipe to a netting chamber located off Dowd Ave.

Outfall and Solids/Floatables Control Facilities: The outfall pipe from the regulator runs about 1,250 feet to the netting chamber, which consists of a single tier system with 3 nets. The flow from the netting chamber is piped about 600 feet to the outlet and discharges at the beginning of the Great Ditch located behind Dowd Avenue. As the discharge point can be influenced by tides, tide gates are provided at the regulator and the netting chamber. There are an estimated 7 storm connections to the outfall pipe downstream of Regulator R002 from the separate storm sewers for the Progress Street and Dowd Avenue area.

Diversions to and from Other Basins: There are no interconnections to adjacent basins.

CSO Drainage Basin 029

General description: CSO Basin 029 is shown on Figure 2-10 and covers approximately 76 acres. Basin 029 is interconnected with Basin 030, with Regulator R030 serving as a relief overflow diversion. The Front Street trunk sewer extends from Regulator R030 to R029 as an incoming combined sewer and collects branch flows along its route.

Significant Indirect Users: There are no SIUs in this drainage basin.

Regulator: The Front Street trunk sewer ends at Regulator R029, which discharges dry weather flows to the adjacent Easterly Interceptor. Overflow control during wet weather events is provided by a 48" wide by 48" high square opening with an invert elevation of EL -0.80' NAVD88 and a 48" diameter overflow pipe to a netting chamber located in Veterans Waterfront Memorial Park.

Outfall and Solids/Floatables Control Facilities: The outfall pipe from the regulator runs about 200 feet to the netting chamber, which consists of a single tier system with 3 nets. After the flow passes through the netting chamber, the flow travels another 100 feet to an outlet discharge at the mouth of the Elizabeth River. As the outfall pipe can be tidally influenced, tide gates are

provided at the regulator and the netting chamber. There are no known storm sewer connections to the outfall downstream of Regulator R029.

Diversions to and from Other Basins: Basin 029 receives combined sewer flows from Basin 030 through the Front Street trunk sewer.

CSO Drainage Basin 030

General description: CSO Basin 030 is shown on Figure 2-10 and covers approximately 19 acres. Basin 030 is interconnected with Basin 029, with Regulator R030 serving as a relief diversion. The Front Street trunk sewer extends from Regulator R030 to R029 as an incoming combined sewer and collects branch flows along its route. Basin 030 surrounds East Jersey Street, from the New Jersey Turnpike to the Arthur Kill.

Significant Indirect Users: There are no SIUs in this drainage basin.

Regulator: The incoming sewer to Regulator R030 is a 30" wide by 45" high brick egg masonry sewer that continues down Front Street as the trunk sewer in Basin 029. There is no diversion to the interceptor at Regulator R030. Overflow control during wet weather events is provided by a 48" diameter opening with an invert elevation of EL 3.71' NAVD88 and a 48" diameter overflow pipe.

Outfall and Solids/Floatables Control Facilities: The outfall pipe from the regulator runs about 150 feet to a netting chamber, which consists of a single tier system with 3 nets. After the flow passes through the netting chamber, the flow travels another 150 feet to an outlet discharge on the Arthur Kill. As the outfall pipe can be tidally influenced, a tide gate is provided at the netting chamber. There is one storm sewer connection on the outfall downstream of Regulator R030.

Diversions to and from Other Basins: Basin 030 sends combined sewer flows to Basin 029 through the Front Street trunk sewer.

CSO Drainage Basin 031

General description: CSO Basin 031 is shown on Figure 2-10 and covers approximately 60 acres. The area is served through branch sewers that connect to the Livingston Street trunk sewer before entering the regulator. Storm drainage in the area is partially separated, with a large storm sewer along Broadway conveying stormwater from that street and the New Jersey Turnpike to a separate storm outfall discharge on the Arthur Kill.

Significant Indirect Users: There are no SIUs in this drainage basin.

Regulator: The Livingston Street trunk sewer ends at Regulator R031, which discharges dry weather flows to the adjacent Easterly Interceptor in Front Street. Overflow control during wet weather events is provided by a 42" wide by 42" high rectangular opening with an invert EL 0.59' NAVD88 and a 36" wide by 54" high brick egg overflow pipe.

Outfall and Solids/Floatables Control Facilities: The outfall pipe from the regulator runs about 120 feet to a netting chamber, which includes a bar screen and of a single tier netting system with 3 nets. After the flow passes through the netting chamber, the flow travels another 210 feet to an outlet discharge on the Arthur Kill. As the outfall pipe can be tidally influenced, a tide gate is provided at the regulator and at the netting chamber. There are no known storm sewer connections on the outfall downstream of Regulator R031.

Diversions to and from Other Basins: There are no interconnections to adjacent basins.

CSO Drainage Basin 032

General description: CSO Basin 032 is shown on Figure 2-10 and covers approximately 65 acres. The area is served through branch sewers that connect to the Magnolia Avenue trunk sewer before entering the regulator. Storm drainage in the area is partially separated, with a separate storm sewer along Magnolia Avenue connecting to the CSO outfall downstream of the regulator.

Significant Indirect Users: Garcia Uniform, Inc., an industrial laundry facility with a permitted flow of 0.009 mgd and a pretreatment program, is located in this CSO basin.

Regulator: Regulator R032 is situated on the 36" wide x 54" high brick egg Magnolia Avenue trunk sewer at the Front Street intersection and discharges dry weather flows to the adjacent Easterly Interceptor. Overflow control during wet weather events is provided by a 42" wide by 42" high rectangular opening with an invert EL 4.45' NAVD88 and a 36" wide by 54" high brick egg overflow pipe.

Outfall and Solids/Floatables Control Facilities: The outfall pipe from the regulator runs about 20 feet to a netting chamber, comprised of a single tier netting system with 2 nets. After the flow passes through the netting chamber, the flow travels another 230 feet to an outlet discharge on the Arthur Kill. As the outfall pipe can be tidally influenced, a tide gate is provided at the regulator and at the netting chamber. A large separate storm sewer connects to the outfall downstream of Regulator R032.

Diversions to and from Other Basins: There are no interconnections to adjacent basins.

CSO Drainage Basin 034

General description: CSO Basin 034 is shown on Figure 2-11 and is divided into 2 sub-basins corresponding to the 2 regulators sharing this CSO outfall. Branch sewers in the area connect to the Trumbull Street / Sixth Street trunk sewer. Basin 034 is also interconnected with CSO Basin 039, with Regulator R039 serving as a relief overflow diversion situated on Trumbull Street / Sixth Street trunk sewer, which continues as the incoming combined sewer to Regulator R034B. Dry weather flows are diverted to the Easterly Interceptor at Regulator R034B, but wet weather flows connect back into the trunk sewer and continue to Regulator R034A and Outfall 034A.

The area of the Regulator R034A sewershed (Sub-basin 034A) is about 102 acres and the area of the Regulator R034B sewershed (Sub-basin 034B), is about 75 acres, for a total area of 177 acres. The area served by Regulator R034A includes properties within the Seaport Industrial Center along First Street and its branch sewers east of Port Avenue. An area along Slater Drive has a separate sanitary sewer connection to the East Side Industrial branch interceptor, downstream of the regulator, and separate storm sewers to Newark Bay. Storm drainage in Sub-basin 034B is partially separated, with storm drains that connect to a separate storm trunk sewer running adjacent to Outfall 039 towards Schiller Street and the Great Ditch.

Significant Indirect Users: Olympia Trails Bus Co., Inc., a bus garage facility with a permitted flow of 0.0069 mgd and a pretreatment program, is located in this CSO basin, namely Sub-basin 034A.

Regulators: Regulator R034B is situated on the 48" wide x 72" high brick egg Trumbull Street / Sixth Street trunk sewer in the vicinity of Second Street and discharges dry weather flows to the adjacent Easterly Interceptor. Overflow control during wet weather events is provided by a 48" wide by 38" high rectangular opening with an invert EL 2.30' NAVD88, which then connects back to the trunk sewer.

The trunk sewer from R034B continues approximately 2,500 feet along Trumbull Street and Puleo Plaza to Regulator R034A located near the Newark Bay. Dry weather flows are diverted through the East Side Industrial branch interceptor to the Easterly Interceptor at Front Street and Port Avenue. Overflow control during wet weather events is provided by a 60" diameter opening with an invert EL -3.00' NAVD88, with a 60" diameter overflow pipe.

Outfall and Solids/Floatables Control Facilities: The outfall pipe from Regulator R034A runs about 150 feet to a netting chamber, comprised of a 2-tier netting system with 2 nets on each level. After the flow passes through the netting chamber, the flow travels another 230 feet to an outlet discharge on the Arthur Kill. As the outfall pipe can be tidally influenced, a tide gate is located at the netting chamber and Regulators R034A and R034B. There are no known storm sewer connections to the outfall downstream of Regulator R034A.

Diversions to and from Other Basins: CSO Basin 034, specifically Sub-basin 034B, receives combined sewage from CSO Basin 039. Overflows from Sub-basin 034B are tributary to Sub-basin 034A, discharging through CSO Outfall 034A.

CSO Drainage Basin 039

General description: CSO Basin 039 is shown on Figure 2-11 and has an area of approximately 245 acres. Branch sewers in the area connect to the Trumbull Street / Sixth Street trunk sewer. Basin 039 is interconnected with CSO Basin 034, with Regulator R039 serving as a relief overflow diversion situated on the Trumbull Street / Sixth Street trunk sewer, which continues as the incoming combined sewer to Regulator R034B. Dry weather flows are diverted to the Easterly Interceptor at Regulator R034B. CSO Outfall 039 runs from Regulator R039 along Dowd Avenue and through easements east of Schiller Street to the Great Ditch.

Significant Indirect Users: 3 SIUs are located in this CSO: 1) Deb-El Food Products, LLC, an egg dehydrating facility with a permitted flow of 0.015 mgd and a pretreatment program; 2) Michael Foods, Inc. - Jersey Pride, an egg processing facility with a permitted flow of 0.2008 mgd and a pretreatment program; and 3) Mastercraft Metal Finishing, a phonographic masters manufacturing facility with a permitted flow of 0.001 mgd and a pretreatment program.

Regulators: Regulator R039 is situated on the 48" wide x 72" high brick egg Trumbull Street / Sixth Street trunk sewer at Fourth Street and the trunk sewer continues southeast on Trumbull Street to Basin 034. There is no diversion to the interceptor at Regulator R039. Overflow control during wet weather events is provided by a 36" diameter opening with an invert EL 5.30' NAVD88, which then connects to a 36" diameter RCP outfall pipe.

Outfall and Solids/Floatables Control Facilities: Regulator R039 is equipped with a static bar screen at the overflow outlet for S/F control. The outfall pipe from Regulator R039 runs about 2,550 feet to the CSO 039A discharge point along the Great Ditch, past the northern end of Schiller Street. Tides may influence the outlet pipe, but a tide gate structure is reported to exist downstream along the ditch. It is likely that separate storm sewers connect to the outfall pipe downstream of Regulator R039.

Diversions to and from Other Basins: CSO Basin 039 sends combined sewage to CSO Basin 034, Regulator R034B, through the Trumbull Street / Sixth Street trunk sewer.

CSO Drainage Basin 035 (043)

General description: CSO Basin 035 is shown on Figure 2-12 and has an area of approximately 120 acres. Branch sewers in the area connect to the Third Avenue trunk sewer. The sewershed for CSO Outfall 035A is the same as that for Outfall 043A as Regulator R043 is an emergency relief overflow located on Outfall 035A. Basin 035 is also interconnected with

CSO Basin 038, with Regulators R038A and B serving as overflow diversions for the Third Avenue trunk sewer, which is the incoming combined sewer to Regulator R035. Dry weather flows are diverted to the Easterly Interceptor at Regulator R035.

Significant Indirect Users: Erie Street Former MGP Site, a groundwater remediation facility with a permitted flow of 0.05 mgd and a pretreatment program, is located in this CSO basin.

Regulators: Regulator R035 is situated on the Third Avenue trunk sewer at the intersection with South First Street and discharges dry weather flows to the adjacent Easterly Interceptor. Overflow control during wet weather events is provided by a 60" long broad crested weir at EL - 3.60' NAVD88, which then connects to a 60" diameter outfall pipe.

Regulator R043 is situated a short distance from R035 on this 60" diameter outfall pipe. Regulator R043 provides emergency overflow relief for CSO Outfall 035A through a 48" wide by 36" high rectangular opening at invert EL 3.10' NAVD88. The relief overflow from R043 discharges to a concrete drainage channel that parallels South First Street.

Outfall and Solids/Floatables Control Facilities: The outfall pipe from Regulator R035 continues about 50 feet to a netting chamber, comprised of a 2-tier netting system with 2 nets on each level. After the flow passes through the netting chamber, it continues another 100 feet to an outlet discharge on the Elizabeth River. As the outfall pipe can be tidally influenced, a tide gate is located at the outfall discharge. There are no known storm sewer connections to the outfall downstream of Regulator R035, however the outfall coincides with the ERFDP Drainage Structure No. 1.

Regulator R043 is equipped with a static bar screen at the overflow outlet for S/F control. When active, discharges from the Emergency Relief Outfall 043A flow through a drainage channel that is connected to the ERFDP ponding area upstream of the South Second Street SWPS intake chamber. The drainage channel also carries stormwater runoff from the South First Street roadway to the ponding area.

Diversions to and from Other Basins: CSO Basin 035 receives combined sewage from CSO Basin 038, through the Third Avenue trunk sewer. CSO Basin 035 is equivalent to CSO Basin 043, with Outfall 043A acting as an emergency relief overflow for Outfall 035A.

CSO Drainage Basin 038

General description: CSO Basin 038 is shown on Figure 2-12 and has a total area of approximately 64 acres. The basin is divided into 2 sub-basins corresponding to its 2 regulators. The area of the Regulator R038A sewershed (Sub-basin 038A) is about 58 acres and the area of the Regulator R038B sewershed (Sub-basin 038B), is about 6 acres. Properties along Third Avenue and its branch sewers from Spencer Street to the New Jersey Turnpike are tributary to R038A, while Regulator R038B receives flow through a sewer on Lt. Zamorski Drive from properties along Elizabeth Avenue southeast of the Turnpike.

Branch sewers in the area connect to the Third Avenue trunk sewer. Basin 038 is interconnected with CSO Basin 035, with Regulators R038A and B serving as relief overflow diversions for the Third Avenue trunk sewer, which is the incoming combined sewer to Regulator R035. Dry weather flows are diverted to the Easterly Interceptor at Regulator R035. There is no diversion to an interceptor in CSO Basin 038.

Significant Indirect Users: There are no SIUs located in this CSO basin.

Regulators: Regulator R038A is situated on the Third Avenue trunk sewer, below the New Jersey Turnpike overpass, and the trunk sewer continues southeast on Third Avenue to Basin 035. Overflow control during wet weather events is provided by a 36" diameter pipe, with its top half cut open, spanning across an 84" diameter manhole. The weir crest of the open pipe is at EL 2.39' NAVD88 and a 36" diameter outfall pipe is connected to the manhole at invert EL - 2.16.

Regulator R038B is associated with a netting chamber located on Lt. Glenn Zamorski Drive that has a 42" diameter incoming sewer. Regulator R038B diverts dry weather flows through an 8" diameter opening and PVC pipe at invert EL 10.76' NAVD88 to the adjacent local sewer. Wet weather flows continue through the netting chamber and through the outfall pipe southwesterly along Lt. Zamorski Drive, then northwesterly along Third Avenue to a connection on Outfall 038A downstream of Regulator R038A. Overflow control during wet weather events is provided by a 72" long weir across the netting chamber with a crest EL 11.48' NAVD88.

Outfall and Solids/Floatables Control Facilities: The outfall pipe from Regulator R038A continues about 90 feet to a netting chamber with 1 net. After the flow passes through the netting chamber, it continues another 1,300 feet to an outlet discharge on the Elizabeth River. As the outfall pipe can be tidally influenced, a tide gate is located at the outfall discharge and the netting chamber. CSO Outfall 038A is connected with the ERFDP Drainage Structure No. 7 and there are also separate storm sewer connections to the outfall pipe downstream of Regulator R038A.

Regulator R038B is associated with a netting chamber with a single net. The outfall pipe from Regulator R038B continues approximately 1,100 feet downstream before connecting to CSO Outfall 038A downstream of Regulator R038A.

Diversions to and from Other Basins: CSO Basin 038 sends combined sewage to CSO Basin 035 through the Third Avenue trunk sewer.

CSO Drainage Basin 037

General description: CSO Basin 037 is shown on Figure 2-12 and has a total area of approximately 86 acres. The basin is divided into 2 sub-basins corresponding to its 2 regulators. The Regulator R037A sewershed (Sub-basin 037A) is about 15 acres and the Regulator R037B sewershed (Sub-basin 037B), is about 70 acres. Branch sewers in the area connect to the Bayway trunk sewer. Regulators R037A and B are located on this trunk sewer and divert dry weather flows to the Bayway branch interceptor that then connects to the Easterly Interceptor. Wet weather flows from Regulator R037B connect back into the Bayway trunk sewer, which continues as the incoming sewer to Regulator R037A. An area of properties along the Bayway branch interceptor are connected to the branch interceptor, creating a separate sewer area adjacent to Basin 037.

Significant Indirect Users: There are no SIUs located in this CSO basin.

Regulators: Regulator R037B is situated on the Bayway trunk sewer, northwest of South Front Street, and the trunk sewer continues southeast on Bayway to R037A. Regulator R037B is coincident with a S/F control netting facility and dry weather flows are discharged through a 24" diameter pipe connected to the Bayway branch interceptor. Overflow control during wet weather events is provided by a by a 72" diameter opening at invert EL -1.82' NAVD88, with a 72" diameter outfall pipe that connects back to the trunk sewer.

The trunk sewer from R037B continues approximately 400 feet along Bayway to Regulator R037A located southeast of South Front Street. Dry weather flows are diverted through the Bayway branch interceptor to the Easterly Interceptor. Overflow control during wet weather

events is provided by a 48" diameter opening at invert EL -3.30' NAVD88, with a 72" diameter brick overflow pipe.

Outfall and Solids/Floatables Control Facilities: A netting chamber with 3 nets on a single level control solids/floatables for the basin. The outfall pipe from the netting chamber runs approximately 950 feet to the outfall discharge on the Arthur Kill. As the outfall pipe can be tidally influenced, a tide gate is provide at Regulator R037A and Regulator R037B.

Diversions to and from Other Basins: There are no interconnections to adjacent basins.

2.9.2 Westerly Interceptor Drainage Basins

CSO Drainage Basin 003

General description: CSO Basin 003 is shown on Figure 2-13 and covers a total area of approximately 339 acres. The basin is divided into 2 sub-basins corresponding to its 2 regulators. The area of the Regulator R003A sewershed (Sub-basin 003A) is about 220 acres and the area of the Regulator R003B sewershed (Sub-basin 003B), is about 119 acres. These area values do not include the 120 acres associated with the 42" diameter Roselle Park storm sewer connection at Park Avenue. The Roselle Park storm sewer drainage area connects at the upstream end of Sub-basin 003A and increases its storm runoff contribution by approximately 120 acres.

The Westfield Avenue / Park Avenue trunk sewer flows easterly to Regulator R003A, while the Grove Street / Pennington Street / Elmora Avenue trunk sewer flows northerly to R003B. Several branch sewers in this vicinity flow directly to the JMEUC Original and Supplemental Trunk Sewer. Regulator R003B is positioned upstream of R003A, with the R003B dry weather flow being tributary to the R003A incoming sewer and the R003B overflow pipe connecting with the R003A overflow at a junction chamber in Westfield Avenue.

Basin 003 is interconnected with CSO Basin 041, with dry weather flows from Regulator R003A continuing downstream to Regulator R041 through the Orchard Street / Morris Avenue trunk sewer. There is no diversion to an interceptor in CSO Basin 003; dry weather flows are diverted to the Westerly Interceptor further downstream at Regulator R005.

Significant Indirect Users: Actavis Elizabeth LLC., a generic pharmaceuticals manufacturing facility with a permitted flow of 0.0076 mgd and a pretreatment program, is located adjacent to this CSO basin, but flows to a branch sewer directly connected to a Joint Meeting trunk sewer.

Regulators: Regulator R003A is situated at the end of the Westfield Avenue / Park Avenue trunk sewer near the Westfield Avenue, Orchard Street, and Magie Avenue intersection. R003A discharges dry weather flows to the Orchard Street / Morris Avenue trunk sewer. Overflow control during wet weather events is provided by two (2) 72" wide by 60" high rectangular openings at invert EL 12.90' NAVD88 associated with the 2-compartment netting facility in Westfield Avenue. A 54" diameter RCP pipe from each compartment discharges to a 60" diameter RCP outfall pipe downstream of the facility.

Regulator R003B is situated along the Grove Street / Pennington Street / Elmora Avenue trunk sewer at the Grove Street and West Grand Street intersection. Dry weather flows from R003B continue through the Grove Street trunk sewer to a junction chamber with Westfield Avenue / Park Avenue trunk sewer. Overflow control during wet weather events is provided by 60" long broad crested weir at EL 11.99' NAVD88, which then connects to a 60" RCP diameter outfall pipe that continues to Regulator R003A.

Outfall and Solids/Floatables Control Facilities: Regulator R003A is associated with a 2-compartment netting facility, with each compartment containing a 2-tier netting system with 2 nets on each level (for a total of 8 nets in the facility). The outfall from the netting facility transitions to a 90" diameter pipe and runs about 2,600 feet to the outlet discharge on west (i.e., right) bank of the Elizabeth River. Groundwater infiltration is known to enter along the long length of CSO Outfall 003A.

The overflow outfall from Regulator R003B is equipped with a netting chamber with 2 nets on a single level. The outfall pipe from the netting chamber runs approximately 800 feet to the junction with the Regulator R003A outfall pipes.

Diversions to and from Other Basins: CSO Basin 003 sends combined sewage to CSO Basin 041 through the Orchard Street / Morris Avenue trunk sewer.

CSO Drainage Basin 041

General description: CSO Basin 041 is shown on Figure 2-13 and covers an area of approximately 238 acres. Branch sewers in the area connect to the Magie Avenue and the Orchard Street / Morris Avenue trunk sewers. Basin 041 is interconnected with CSO Basins 003 and 005, with Regulators R003A and B contributing dry weather flows to a Basin 041 trunk sewer. Dry weather flows then continue through the trunk sewer from Regulator R041 to R005. Regulator R041 serves as an upstream wet weather overflow diversion and dry weather flows are diverted to the Westerly Interceptor at Regulator R005.

Significant Indirect Users: There are no SIUs located in this CSO basin.

Regulators: Regulator R041 is situated on the Orchard Street / Morris Avenue trunk sewer, at the Elizabeth River. It discharges dry weather flows through the Morris Avenue siphon downstream to a trunk sewer tributary to Regulator R005. Overflow control during wet weather events is provided by a 66" diameter opening with invert EL 6.15' NAVD88, which connects to a 90" RCP overflow pipe.

Outfall and Solids/Floatables Control Facilities: The outfall pipe from the regulator runs about 100 feet to the netting chamber, which consists of a 2-tier system with 3 nets on the lower level and 2 nets on the upper level. The overflow from the netting chamber then discharges to the Elizabeth River. There are no known storm sewer connections to the outfall downstream of the regulator.

Diversions to and from Other Basins: CSO Basin 041 receives combined sewage from CSO Basin 003 and sends combined sewer flows to the regulator of Basin 005.

CSO Drainage Basin 005

General description: CSO Basin 005 is shown on Figure 2-14 and covers an area of approximately 189 acres. Branch sewers in the area connect to the downstream portion of the Union Avenue/ Newark Avenue trunk sewer. Basin 005 is interconnected with CSO Basins 003 (through Basin 041), 036, and 041. The Union Avenue/ Newark Avenue trunk sewer extends from Regulator R036A to R005 and collects branch flows within Basin 005 along its route. Flows from the Union Avenue trunk sewer and the Morris Avenue trunk sewer from Basin 041 combine at a junction chamber upstream of Regulator R005.

Significant Indirect Users: There are no SIUs located in this CSO basin.

Regulators: Regulator R005 is situated on Westfield Avenue, east of the Elizabeth River and west of Morris Avenue. It discharges dry weather flows to the upstream end of the Westerly

Interceptor. Overflow control during wet weather events is provided by an 80" long weir at crest EL 5.64' NAVD88, which connects to an 84" diameter RCP overflow pipe.

Outfall and Solids/Floatables Control Facilities: The 84" diameter RCP overflow pipe from Regulator R005 transitions to an 84" wide by 66" high box culvert that runs to a netting facility located adjacent to the river and contains 1-tier system with 3 nets. The outfall discharge outlet at the river is 84" diameter. Storm sewers connect to the outfall pipe downstream of the regulator and the outfall coincides with the ERFCD Drainage Structure No. 67.

Diversions to and from Other Basins: CSO Basin 005 receives combined sewer flows from CSO Basins 003 (via Basin 041), 036, and 041.

CSO Drainage Basin 036

General description: CSO Basin 036 is shown on Figure 2-14 and covers an area of approximately 210 acres. Branch sewers in the area connect to the upstream portion of the Union Avenue/ Newark Avenue trunk sewer. Both Regulator R036A and R036B are located along this trunk sewer and divert wet weather overflows to the same outfall, with R036A positioned approximately 180' downstream of R036B. Basin 036 is interconnected with CSO Basin 005, with the Union Avenue/ Newark Avenue trunk sewer continuing downstream from Regulator R036A as a tributary line to Regulator R005. Regulators R036A and B serve as upstream wet weather overflow diversions and dry weather flows are diverted to the Westerly Interceptor at Regulator R005.

Significant Indirect Users: There are no SIUs located in this CSO basin.

Regulators: Regulator R036B is situated on the trunk sewer along North Broad Street, north of Pingry Place. Overflow control during wet weather events is provided by a 42" diameter opening and RCP at invert EL 13.02' NAVD88, which discharges to the CSO Outfall 036A pipe downstream.

The trunk sewer from R036B continues along North Broad Street to Regulator R036A located at the intersection with Salem Avenue. Overflow control during wet weather events is provided by a 42" diameter opening and RCP at invert EL 13.40' NAVD88, which discharges to the CSO Outfall 036A pipe downstream.

Outfall and Solids/Floatables Control Facilities: Regulator R036A is equipped with a static bar screen at the overflow outlet for S/F control. Overflows from Regulator R036B pass through a 2-tier netting facility with 2 nets on each level. CSO Outfall 036 runs over 2,600 feet to a 120" square outlet on the Elizabeth River at Irvington Avenue and Dod Court. There are numerous storm sewer connections to Outfall 036A downstream of the regulators.

Diversions to and from Other Basins: CSO Basin 036 sends combined sewer flows to the trunk sewer of CSO Basin 005.

CSO Drainage Basin 008

General description: CSO Basin 008 is shown on Figure 2-15 and covers approximately 23 acres. The basin extends along the north and south sides of the former railroad tracks paralleling Westfield Avenue, from Chilton Street to the Elizabeth River. Branch sewers deliver flows from Westfield Avenue, Cherry Street, Lowden Street, and West Grand Street to the regulator located on the west, or right, bank of the river on West Grand Street.

Significant Indirect Users: There are no SIUs located in this CSO basin.

Regulators: Regulator R008 has 2 incoming 12" diameter sewer connections and discharges dry weather flows through the West Grand Street siphon across the river and through the West Jersey Street / West Grand Street branch interceptor to the Westerly Interceptor. Overflow control during wet weather events is provided by an 18" diameter opening at invert EL 4.80' NAVD88 and 18" diameter overflow pipe.

Outfall and Solids/Floatables Control Facilities: Regulator R008 is equipped with a static bar screen for S/F control. The outfall pipe runs about 35 feet to the CSO 008A discharge point on the right bank of the Elizabeth River. Storm sewers connect to the outfall pipe downstream of the regulator and the outfall coincides with the ERFDP Drainage Structure 61.

Diversions to and from Other Basins: There are no interconnections to adjacent basins.

CSO Drainage Basin 010

General description: CSO Basin 010 is shown on Figure 2-15 and covers approximately 76 acres. The area is served by branch sewers that connect to a 24" wide by 36" high brick egg sewer in Murray Street before entering the regulator.

Significant Indirect Users: There are no SIUs located in this CSO basin.

Regulators: Regulator R010 is situated at the Murray Street and Cherry Street intersection and discharges dry weather flows through the Rahway Avenue / Cherry Street branch interceptor to the Westerly Interceptor. Overflow control during wet weather events is provided by a 24" long weir at crest EL 12.80' NAVD88 and 24" wide by 36" high brick egg outfall pipe.

Outfall and Solids/Floatables Control Facilities: The overflow pipe from Regulator R010 transitions to 48" diameter RCP that runs to a netting facility located adjacent to the river and contains a 1-tier system with 2 nets. The outfall discharge outlet at the river is 48" diameter. Storm sewers connect to the outfall pipe downstream of the regulator.

Diversions to and from Other Basins: There are no interconnections to adjacent basins.

CSO Drainage Basin 011

General description: CSO Basin 011 is shown on Figure 2-15 and covers approximately 34 acres. The basin extends north and south of a local sewer in Rahway Avenue that collects flows from Elmora Avenue to the Elizabeth River before entering the regulator. The overflow outfalls for CSO Basins 011 and 013 were consolidated as part of the solids/floatables control project. As such, the overflow pipe from Regulator R011 joins the overflow from R013 and the consolidated outfall discharge point is identified in the NJPDES CSO Permit by serial number 013A.

Significant Indirect Users: There are no SIUs located in this CSO basin.

Regulators: Regulator R011 is located in Rahway Avenue, west of the Burnet Street intersection, and discharges dry weather flows through the Rahway Avenue / Cherry Street branch to the Westerly Interceptor. Flow can also go to the Pearl Street / Burnet Street branch through relief connections. Overflow control during wet weather events is provided by a 24" diameter opening at invert EL 6.71' NAVD88 off a 42" diameter RCP storage pipe that then continues as a 24" diameter overflow pipe to a junction manhole with the R013 overflow pipe.

Outfall and Solids/Floatables Control Facilities: The overflow pipe from the junction manhole runs to a 1-tier, 1 net netting facility located on the south side Rahway Avenue, east of Burnet Street. From the netting chamber, the outfall pipe flows to the CSO 013A discharge point on the

south side of the Elizabeth River. No storm sewers are known to connect to the outfall pipe downstream of the regulator.

Diversions to and from Other Basins: Overflows from CSO Basin 011 are consolidated with overflows from Basin 013 to the CSO Outfall 013A discharge point.

CSO Drainage Basin 012

General description: CSO Basin 012 is shown on Figure 2-15 and covers approximately 9 acres. The basin extends north and south of Rahway Avenue between the Elizabeth River and Broad Street. Both Regulator R012A and R012B are located along the sewer in Rahway Avenue, with R012A positioned approximately 110' downstream of R012B. Dry weather flows are first diverted at R012B and combined flows from R012B continue downstream to R012A.

Significant Indirect Users: There are no SIUs located in this CSO basin.

Regulators: Regulator R012B is situated upstream of R012A on the same Rahway Avenue sewer line. Dry weather flows discharge through an 8" diameter pipe at invert EL 0.40' NAVD88 that connects with a DWF pipe from R012A and continues to the Westerly Interceptor at Elizabethtown Plaza. Overflow control during wet weather events is provided by an 18" diameter opening at invert EL 2.70' NAVD88 off a 42" diameter RCP storage pipe that then continues as the 18" diameter incoming sewer to R012A.

Regulator R012A is situated on Rahway Avenue, on the east side of the river, and is associated with a bar screen and tide gate chamber installed for S/F control. Dry weather flows discharge through an 8" diameter pipe at invert EL 1.63' NAVD88 that connects with a DWF pipe from R012B. Overflow control during wet weather events is provided by a 24" diameter opening at invert EL 2.78' NAVD88 at the tide gate chamber and an outfall pipe that is a continuation of the incoming sewer.

Outfall and Solids/Floatables Control Facilities: Regulator R012A is equipped with a static bar screen for S/F control. The outfall pipe runs about 35 feet to the CSO 012A discharge point on the left bank of the Elizabeth River. A 24" diameter tide gate is provided with the S/F control structures. Storm sewers connect to the outfall pipe downstream of the regulator.

Diversions to and from Other Basins: There are no interconnections to adjacent basins.

CSO Drainage Basin 013

General description: CSO Basin 013 is shown on Figure 2-15 and covers approximately 24 acres. The basin extends east and west along Fay Avenue and Burnet Street, from Grove Street to the Elizabeth River. The overflow outfalls for CSO Basins 011 and 013 were consolidated as part of the solids/floatables control project, so that the overflow pipe from Regulator R013 joins the overflow from R011 and the consolidated outfall discharge point is identified in the NJPDES CSO Permit by serial number 013A.

Significant Indirect Users: There are no SIUs located in this CSO basin.

Regulators: Regulator R013 is located in Burnet Street, south of the Rahway Avenue intersection, and discharges dry weather flows through the Pearl Street / Burnet Street branch to the Westerly Interceptor. Overflow control during wet weather events is provided by a 24" long weir at invert EL 13.97' NAVD88 that then continues as a 24" diameter overflow pipe to a junction manhole with the R011 overflow pipe.

Outfall and Solids/Floatables Control Facilities: The outfall pipe from the junction manhole runs to the same 1-tier, 1 net netting facility serving Basin 011, located on the south side of Rahway

Avenue, east of Burnet Street. From the netting chamber, a 36" diameter RCP outfall flows to the CSO 013A discharge point on the south side of the Elizabeth River. No storm sewers are known to connect to the outfall pipe downstream of the regulator.

Diversions to and from Other Basins: Overflows from CSO Basin 013 are consolidated with overflows from Basin 011 and discharge through the CSO Outfall 013A location.

CSO Drainage Basin 014

General description: CSO Basin 014 is shown on Figure 2-15 and covers approximately 12 acres. The basin extends east and west along Broad Street between West Jersey Street and Elizabeth Avenue. The area is served by branch sewers that connect to an 18" diameter sewer in Broad Street before entering the regulator.

Significant Indirect Users: There are no SIUs located in this CSO basin.

Regulators: Regulator R014 is located at the intersection of Broad Street and Elizabeth Avenue and discharges dry weather flows to the adjacent Westerly Interceptor. Overflow control during wet weather events is provided by an 18" diameter opening at invert EL 6.17' NAVD88 off a 60" diameter RCP storage pipe that then continues as the 18" diameter outfall pipe to the netting chamber.

Outfall and Solids/Floatables Control Facilities: The overflow pipe from Regulator R014 runs to a 1-tier, 1 net netting facility located along the easterly curb line of South Broad Street, south of Rahway Avenue. From the netting chamber, a 36" diameter outfall pipe flows southerly along South Broad Street to the CSO 014A discharge point on the north side of the Elizabeth River. A storm sewer connects to the outfall pipe downstream of the regulator.

Diversions to and from Other Basins: There are no interconnections to adjacent basins.

CSO Drainage Basin 016

General description: CSO Basin 016 is shown on Figure 2-15 and covers approximately 38 acres. Branch sewers deliver flows from Race Street, Washington Avenue, Ely Street, and Liberty Street that connect to various sewers in Pearl Street and converge at the regulator.

Significant Indirect Users: There are no SIUs located in this CSO basin.

Regulators: Regulator R016 is located along the north side of Pearl Street in the vicinity of Washington Avenue and discharges dry weather flows to the Westerly Interceptor through the Pearl Street / Burnet Street branch interceptor. Overflow control during wet weather events is provided by a 30" long weir at crest EL 5.43' NAVD88 and 24" wide by 36" high brick egg outfall pipe.

Outfall and Solids/Floatables Control Facilities: The overflow pipe from Regulator R016 transitions to 36" diameter RCP that runs to a netting facility located adjacent to the river behind an apartment complex and commercial retail center. The netting chamber contains 2 nets on a single level. A 36" diameter tide gate is provided with the S/F control structure. The CSO 016A outfall discharge outlet is 36" diameter on the south side of the Elizabeth River. Storm sewers connect to the outfall pipe downstream of the regulator and the outfall coincides with the ERFCD Drainage Structure No. 44.

Diversions to and from Other Basins: There are no interconnections to adjacent basins.

CSO Drainage Basin 021

General description: CSO Basin 021 is shown on Figure 2-16 and covers approximately 3 acres. The tributary flow for the basin consists of short reaches of local sewers on South Spring Street and Third Avenue and a significant portion of the adjacent area has separate storm sewers. Basin 021 is interconnected with CSO Basin 022, with Regulator R021 providing an overflow diversion from the combined sewer that connects into the Basin 022 trunk sewer. There is no diversion to an interceptor in CSO Basin 021; dry weather flows are diverted to the Westerly Interceptor through the South Street branch from Regulator R022.

Significant Indirect Users: There are no SIUs located in this CSO basin.

Regulators: Regulator R021 is located on Third Avenue, south of South Spring Street and is associated with a bar screen chamber for S/F control. Overflow control during wet weather events is provided by a 16" diameter opening at invert EL 2.80' NAVD88 that discharges to a 16" overflow pipe.

Outfall and Solids/Floatables Control Facilities: Regulator R021 is equipped with a static w bar screen for S/F control. The overflow pipe transitions to 24" diameter RCP that runs to the CSO 021A discharge point on the left bank of the Elizabeth River. Storm sewers connect to the outfall pipe downstream of the regulator and the outfall coincides with the ERFCD Drainage Structure No. 32.

Diversions to and from Other Basins: CSO Basin 021 sends combined sewage to Basin 022.

CSO Drainage Basin 022

General description: CSO Basin 022 is shown on Figure 2-16 and covers approximately 168 acres. Branch sewers in the area connect to the Reid Street / East Grand Street trunk sewer. Basin 022 is interconnected with CSO Basin 021, with the combined sewer from Regulator R021 running to the Basin 022 trunk sewer. Dry weather flows are diverted to the Westerly Interceptor through the South Street siphon and branch interceptor.

Significant Indirect Users: 2 SIUs are located in this CSO basin: 1) 814 Americas, Inc. (a division of Patrick Cudahy Inc.), a meat processing facility with a permitted flow of 0.01 mgd and a pretreatment program; and 2) Magnolia Beef Co., a meat processing facility with a permitted flow of 0.0013 mgd and a pretreatment program.

Regulators: Regulator R022 is located on South Street, west of the Fourth Avenue and South Spring Street intersection. The regulator is situated on a 48" wide by 72" high brick egg section of the Reid Street / East Grand Street trunk sewer, which continues to the west as the overflow pipe. Dry weather flows are diverted through a 15" pipe that runs to the South Street siphon. Overflow control during wet weather events is provided by a 48" long weir at crest EL 0.20' NAVD88.

Outfall and Solids/Floatables Control Facilities: The brick sewer overflow from Regulator R022 transitions to a 60" diameter RCP that runs to a netting facility located adjacent to the river by the South Street SWPS and the siphon inlet chamber. The netting chamber contains 3 nets on a single level. A 60" diameter tide gate is provided with the S/F control structure. From the netting chamber, the outfall pipe connects to the South Street SWPS gravity diversion channel and the station's outlet chamber also serves as the outlet for CSO Outfall 022A. When gravity flow is prevented by high river levels, operation of the pump station is initiated and flow is diverted to a pump chamber and discharged by the pumps to a discharge chamber connected to the outlet structure. The CSO 022A outfall discharge outlet is 48" diameter on the south side of the Elizabeth River. Storm sewers connect to the outfall pipe downstream of the regulator.

Diversions to and from Other Basins: CSO Basin 022 receives combined sewage to Basin 022.

CSO Drainage Basin 026

General description: CSO Basin 026 is shown on Figure 2-16 and covers approximately 111 acres. Branch sewers in the area connect to the John Street / Niles Street trunk sewer and dry weather flows are diverted to the Westerly Interceptor through the Palmer Street siphon and branch interceptor.

Significant Indirect Users: There are no SIUs located in this CSO basin.

Regulators: Regulator R026 is located at the west end of John Street, adjacent to the Elizabeth River. The regulator is situated on a 39" wide by 48" high brick egg section of the John Street / Niles Street trunk sewer and dry weather flows are diverted through a 15" pipe that parallels the left bank of the river to the Palmer Street siphon. Overflow control during wet weather events is provided by a 60" long weir at crest EL 0.95' NAVD88 and a 42" RCP overflow pipe.

Outfall and Solids/Floatables Control Facilities: The overflow pipe from Regulator R026 connects to an adjacent netting facility that contains 3 nets on a single level. The CSO 026A outfall discharge is 42" diameter on the left bank of the Elizabeth River, which is fitted with a 42" diameter tide gate. Storm sewers connect to the outfall pipe downstream of the regulator and the outfall coincides with the ERFDP Drainage Structure No. 20.

Diversions to and from Other Basins: There are no interconnections to adjacent basins.

CSO Drainage Basin 027/028

General description: CSO Basin 027/028 is shown on Figure 2-17 and covers approximately 216 acres. Branch sewers in the area connect to the Summer St / South Elmora Ave trunk sewer and dry weather flows are diverted to the Westerly Interceptor along Clarkson Avenue at Summer Street. Two (2) overflow outfall pipes exit the regulator structure, so the basin is associated with the discharges through CSO Outfall 027A and CSO Outfall 028A.

Significant Indirect Users: There are no SIUs located in this CSO basin.

Regulators: Regulator R027/028 is located on Summer Street, west of Clarkson Avenue, and 2 incoming sewer lines converge at the regulator. Dry weather flows are diverted through a 15" pipe that connects to the adjacent Westerly Interceptor. Overflow control at the regulator for the 2 outfall pipes is provided by a 76" long weir at crest EL -2.46' NAVD88. Further overflow control occurs for Outfall 027A with the 60" diameter pipe opening at invert EL -0.77 NAVD88 and for Outfall 028A with the 48" diameter pipe opening at invert EL -2.56' NAVD88.

Outfall and Solids/Floatables Control Facilities: The overflow pipe for Outfall 027A runs along the north side of Summer Street to a netting facility situated next to the river. The netting chamber consists of a 2-tier system, each with 2 nets for a total of 4 nets. A 66" diameter tide gate is provided with the S/F control structure. The CSO Outfall 027A discharge point is 66" diameter, with a tide gate at the outlet structure on the right bank of the Elizabeth River and the outfall coincides with the ERFDP Drainage Structure No. 15. Outfalls 027A and 028A are interconnected upstream of the discharge points and storm sewers connect to the outfall pipes downstream of the regulator.

The overflow pipe for Outfall 028A runs along the opposite side of Summer Street to a separate netting facility at the river. The netting chamber for Outfall 028A consists of a single tier system with 3 nets. A 48" diameter tide gate is provided with the S/F control structure. The CSO Outfall

028A discharge point is 66" diameter, with an outlet structure on the right bank of the Elizabeth River. Outfalls 027A and 028A are interconnected upstream of the discharge points and storm sewers connect to the outfall pipes downstream of the regulator.

Diversions to and from Other Basins: There are no interconnections to adjacent basins.

CSO Drainage Basin 040

General description: CSO Basin 040 is shown on Figure 2-17 and covers approximately 40 acres. The area corresponds to Pulaski Street, Richmond Street, and Clarkson Avenue, north of I-278 and the NJ Turnpike interchange.

Significant Indirect Users: There are no SIUs located in this CSO basin.

Regulators: Regulator R040 is located on the south side of Pulaski Street, west of Clifton Street, and incorporates the netting facility for S/F control. Dry weather flows are diverted through a 15" pipe that connects to the Westerly Interceptor as it parallels the right bank of the Elizabeth River. Overflow control during wet weather events is provided by a 54" diameter opening at invert EL -2.26' NAVD88 for the outfall pipe.

Outfall and Solids/Floatables Control Facilities: Regulator R040 is associated with a netting facility with 3 nets on a single level. A 54" diameter tide gate is provided in the S/F control structure. The CSO Outfall 040A discharge point is 45" diameter, with a tide gate at the outlet structure on the right bank of the Elizabeth River and the outfall coincides with the ERFCD Drainage Structure No. 11. Storm sewers connect to the outfall pipes downstream of the regulator.

Diversions to and from Other Basins: There are no interconnections to adjacent basins.

CSO Drainage Basin 042

General description: CSO Basin 042 is shown on Figure 2-18 and covers a total area of approximately 192 acres. The basin is divided into 4 sub-basins that relate to the corresponding regulator sewersheds. The Regulator R042A, R042B, R042C, and R042D sewersheds (i.e., Sub-basins 042A, 042B, 042C, and 042D) are about 24, 25, 110, and 33 acres, respectively. While each regulator diverts excess flows to a common CSO outfall conduit, Sub-basins 042A and 042D are further interconnected for dry weather flows and Sub-basins 042B and 042C are similarly interconnected. Dry weather flows are diverted towards the Westerly Interceptor at Regulators R042A and R042B, while R042C contributes DWF to R042B and R042D contributes DWF to R042A.

The area is located in the center of the City, where the Bridge Street / Jefferson Avenue trunk sewer conveys flows from local branch sewers to the various control structures. Stormwater drainage in the basin has also been partially separated, particularly in the zone surrounding Jefferson and Madison Avenues, from East Grand Street south to Elizabeth Avenue. A large trunk storm sewer was constructed in this drainage district in the mid-1960s, which serves as the CSO outfall conduit for the excess flows from the regulators and also receives flow from the Arch SWPS.

Regulator R042D provides a relief overflow diversion for the sewershed associated with Regulator R042A, with the DWF pipe continuing through R042D to R042A and then connecting downstream to the Westerly Interceptor. The sewersheds for Regulators R042B and R042C are also interconnected, with the DWF pipe from R042C continuing as a trunk sewer to R042B, from which a dry weather branch sewer extends southerly to the Westerly Interceptor, collecting flow from sanitary lateral connections along the run.

Significant Indirect Users: There are no SIUs located in this CSO basin.

Regulators: Regulator R042A is located at the intersection of Elizabeth Avenue and Bridge Street and consists of chamber constructed over a 42" wide by 63" high brick egg section of the Bridge Street / Jefferson Avenue trunk sewer at an incoming storm sewer crossing. Dry weather flows continue underneath an elevated concrete channel constructed across the chamber to carry wet weather flows. From the regulator, dry weather flows continue to a Westerly Interceptor connection in Bridge Street. Overflow control during wet weather events is provided by a 60" long weir at crest EL 5.73' NAVD88 to a 36" diameter RCP overflow that connects to the 90" diameter RCP CSO Outfall 042 to the west in Elizabeth Avenue.

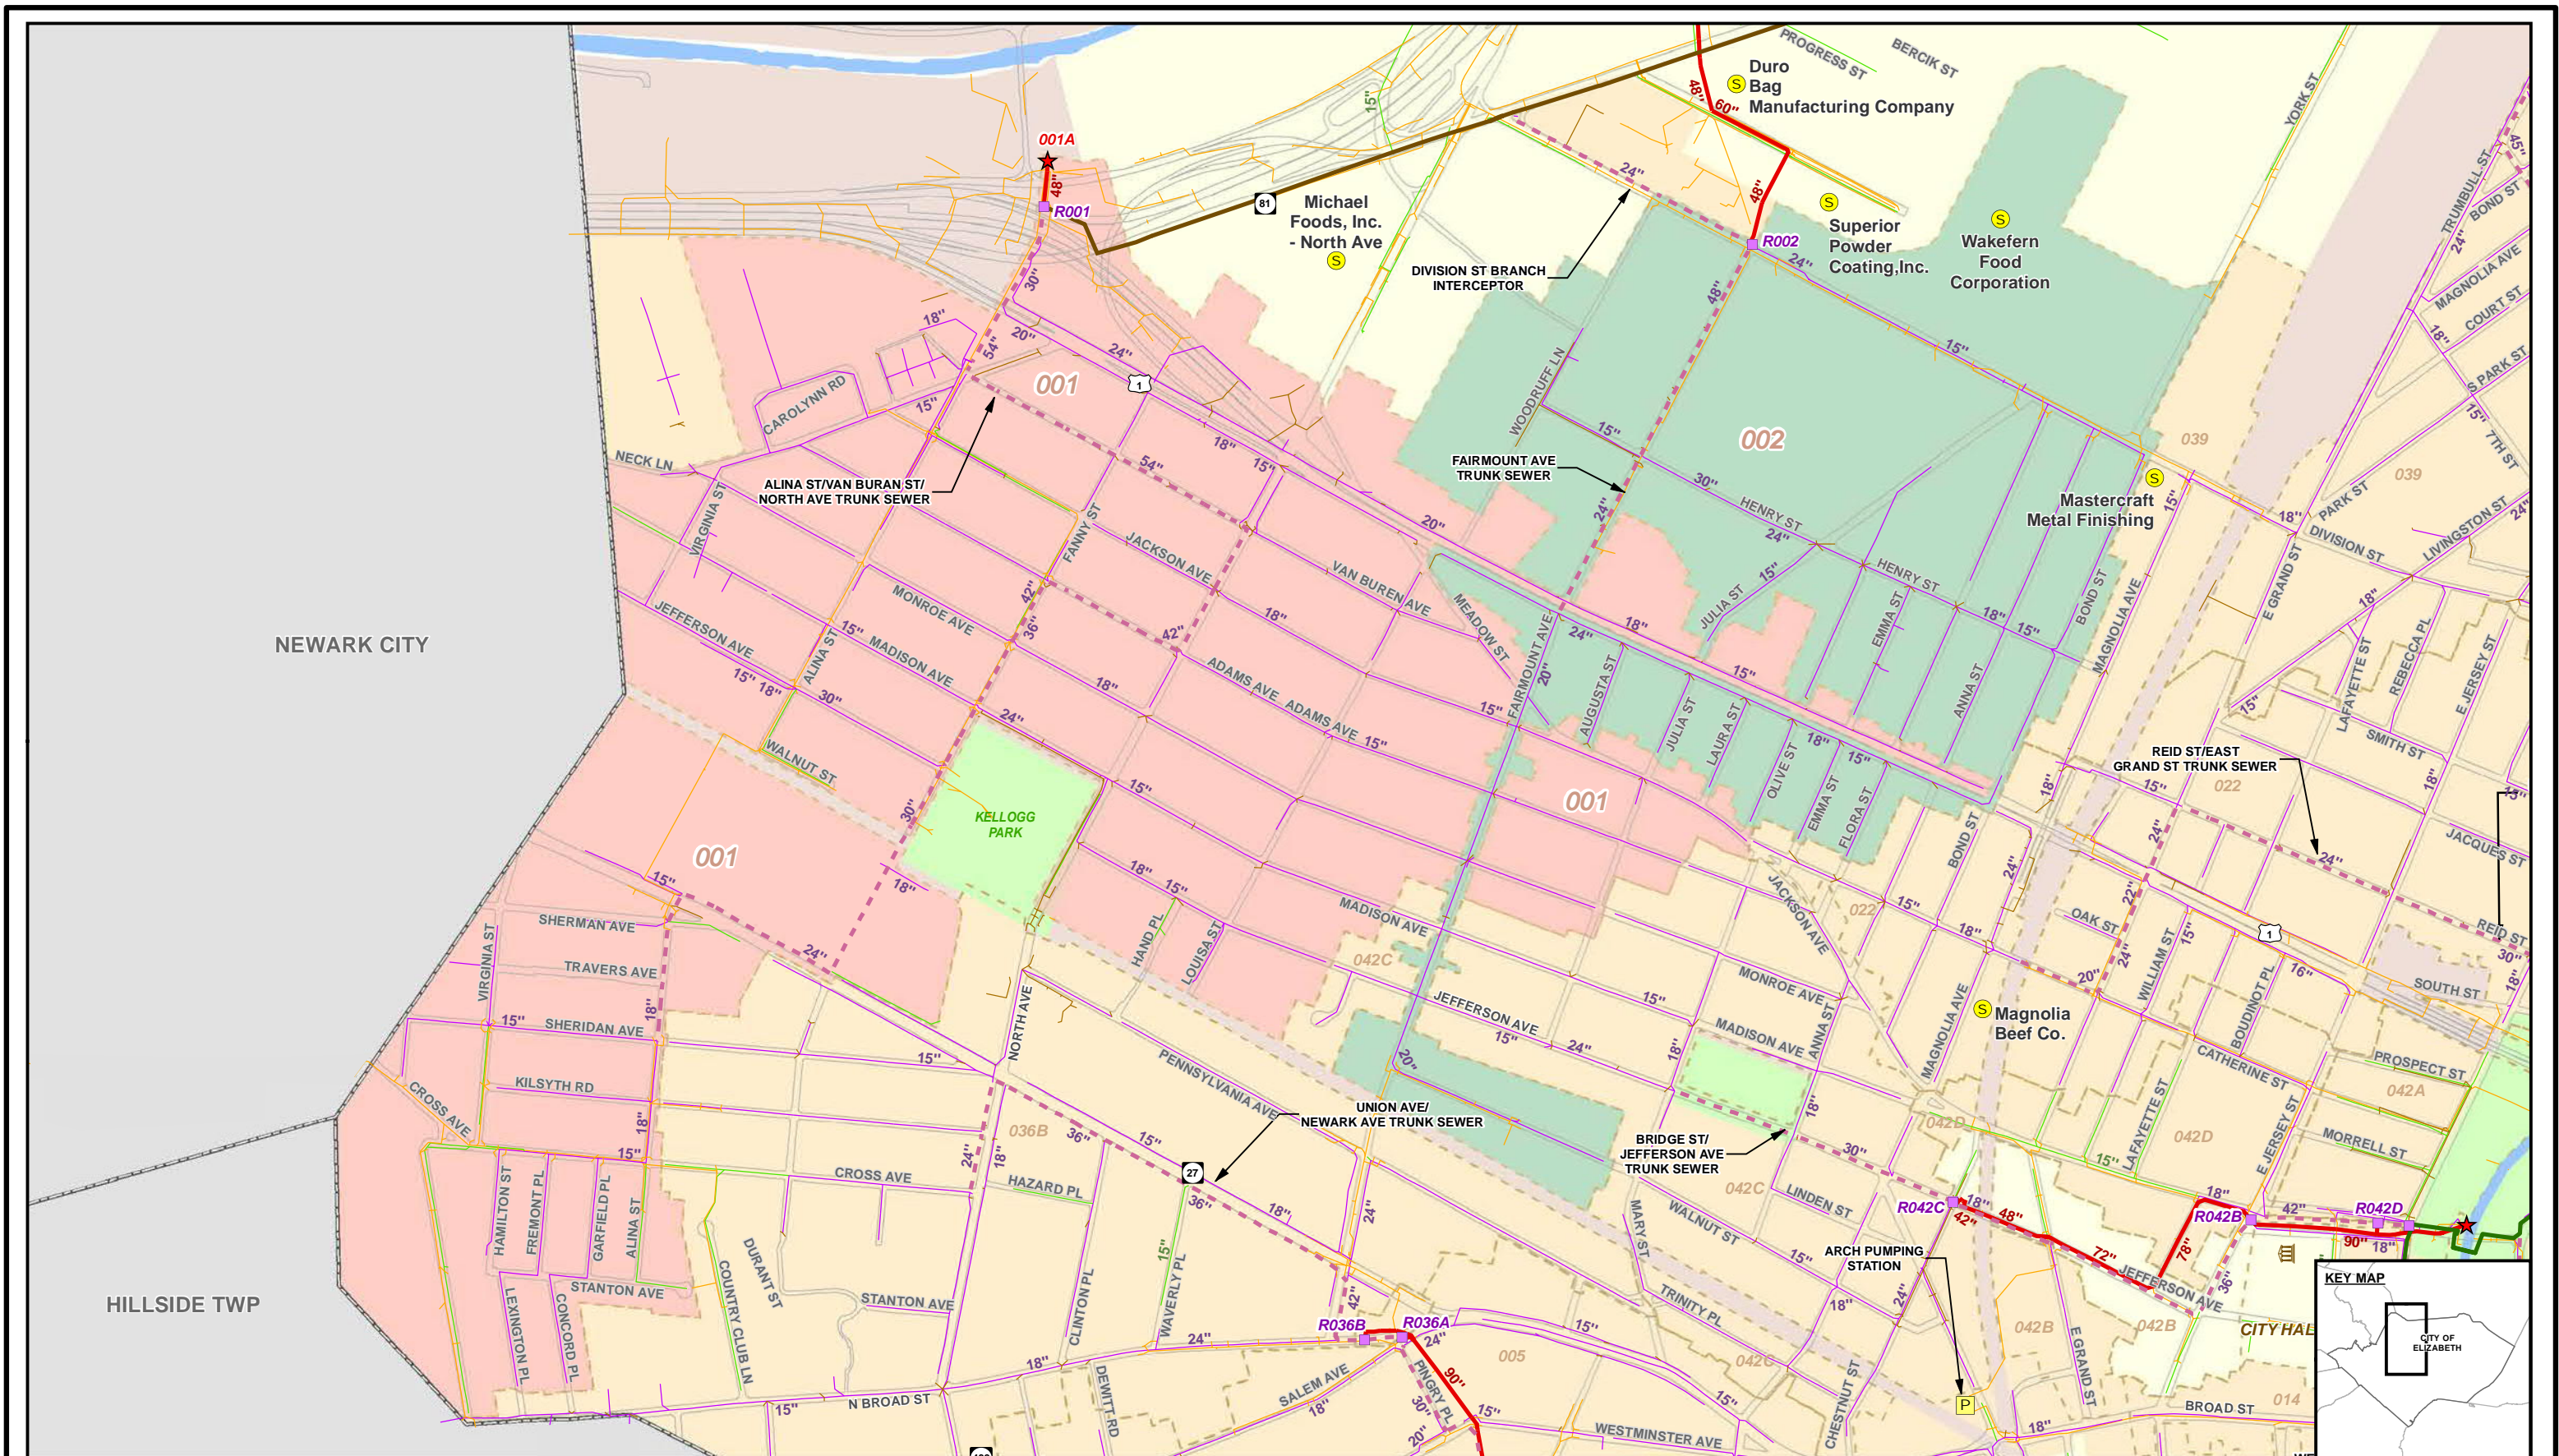

Regulator R042D is situated in Winfield Scott Park on the 42" wide by 63" high brick egg trunk sewer upstream and to the north of R042A. Overflow control is provided by a 42" diameter opening at invert EL 5.34' NAVD88 to a 42" diameter RCP overflow that flows to a netting facility and then connects to the 90" diameter CSO Outfall 042 on the west side of the park.

Regulator R042B is located at the intersection of East Jersey Street and Winfield Scott Plaza and consist of a diversion chamber constructed on a 36" wide by 54" high brick egg section of the Bridge Street / Jefferson Avenue trunk sewer. Dry weather flows are diverted through an 18" pipe that runs south along Winfield Scott Plaza to a Westerly Interceptor connection in Elizabeth Avenue. Wet weather overflow control is provided by a 48" wide by 26" high rectangular opening at invert EL 9.90 to an adjacent chamber on the 78" diameter CSO Outfall 042. The original Bridge Street / Jefferson Avenue trunk sewer is interrupted at Regulator R042B (i.e., a section of the brick sewer was removed, with one end forming the incoming sewer connection to the diversion chamber and other end sealed) and there is no connection at R042B to the remaining brick sewer that continues to R042D.

Regulator R042C is located at the intersection of Jefferson Avenue and Chestnut Street and consists of a diversion chamber constructed on a 30" wide by 45" high brick egg section of the Bridge Street / Jefferson Avenue trunk sewer further upstream from R042B. Dry weather flows are diverted through an 18" pipe that runs south along Jefferson Avenue but transitions back to the original brick trunk sewer that is tributary to R042B. Overflow control is provided by 44" wide by 36" high rectangular opening at invert EL 16.90 to an adjacent chamber on the 42" diameter CSO Outfall 042.

Outfall and Solids/Floatables Control Facilities: Regulators R042A and R042B are each equipped with a static bar screen at the overflow outlet for S/F control. Overflows from Regulators R042C and R042D pass through a netting facility with 2 nets on a single level at each location. The CSO Outfall 042A discharge point is a 113" wide by 72" high elliptical outlet on the left bank of the Elizabeth River, east of Bridge Street. Upstream of the outlet point, a 113" wide flap gate is furnished in a chamber previously associated with a storage module facility for tidal intrusion prevention. Storm sewers connect to the CSO Outfall pipe at several locations along its alignment.

Diversions to and from Other Basins: There are no interconnections to adjacent basins.

2.10 Pumping Station Flows

Flow meters are installed at the Trenton Avenue and Kapkowski Road Pumping Stations and these flows are recorded and reported by E'Town Services, LLC. As the wastewater from the Kapkowski Road PS is conveyed to the Trenton Avenue PS via the Easterly Interceptor, these flows are a component of the Trenton Avenue PS flow measurements. Table 2-17 indicates the average daily flows based on the reported flow values for these stations by month and year for the period from January 2015 to December 2017.

Table 2-17: Trenton Avenue and Kapkowski Pumping Station Flows

Average Daily Flows (mgd)							
Month	Trenton Avenue PS			Kapkowski Road PS			
Year	2015	2016	2017	2015	2016	2017	
January	15.0	15.2	17.6	0.0396	0.0410	0.0546	
February	14.0	20.0	15.4	0.0439	0.0581	0.0467	
March	19.3	15.4	17.1	0.0556	0.0436	0.0445	
April	13.9	13.8	18.6	0.0458	0.0444	0.0481	
May	12.0	13.3	19.4	0.0624	0.0555	0.0644	
June	16.8	13.9	17.6	0.0513	0.0486	0.0602	
July	14.8	14.9	16.7	0.0469	0.0453	0.0539	
August	13.5	13.3	17.1	0.0589	0.0607	0.0548	
September	13.7	12.6	14.4	0.0441	0.0511	0.0522	
October	14.2	13.8	14.1	0.0417	0.0542	0.0633	
November	14.7	14.3	14.4	0.0505	0.0469	0.0492	
December	14.1	16.1	13.7	0.0395	0.0507	0.0447	
Annual Average	14.7	14.7	16.3	0.0484	0.0500	0.0530	

Source: E'Town Services, LLC Operation Reports

From available records since 2005, the annual average flow from the Trenton Avenue PS has varied from 14.0 to 17.6 mgd, with a general decline from 2005 to 2015. The Trenton Avenue PS flow trended at approximately 14.6 mgd from 2012 until 2017. Given the combined sewer contributions, the average daily flows from the station are influenced by variations in precipitation amounts across periods.

In addition to the pumped flows from the Trenton Avenue PS, the flow assessed by Joint Meeting to the City of Elizabeth for billing purposes includes approximately 3,900 equivalent dwelling units tributary from the City and Linden and one process industry and two facilities contributing stormwater runoff.

2.11 Facilities Assessment

Despite the age of the sewer system, prior measures taken to stabilize the interceptor sewers, to investigate and repair known problems in the collector sewers, and to identify and prioritize maintenance concerns in collection, conveyance and pumping facilities have been effective in keeping the system running. However, problem areas do exist which are identified by the frequency of maintenance calls, blockages, collapses requiring emergency repairs, flooding or capacity issues. The potential impacts from sewer asset failures are assessed by the City on a system-wide basis and the criticality of assets and project priorities are determined based on the available information.

The City maintains records of major events that require service to components in the sewer system. Invoices from the sewer system contract operator for emergency events are analyzed to provide insight into maintenance trends. The events are mapped and categorized based on year, type of work, and cost of the repair. Types of work are sub-categorized into replacements, repairs, new installations, and removals as well as by asset type: catch basins and laterals, drainage structures and tide gates, manholes, pump stations, control nets, sewer mains, and other. Geographic concentrations of repairs are reviewed as part of the operations and maintenance (O&M) program and capital improvements planning. Overall, most work orders are sewer main replacement related and distributed evenly across the City.

2.11.1 Collector Sewers

The Elizabeth collector sewers are largely vitrified clay pipe (VCP) and brick egg pipes with brick manholes and catch basins, reflecting the age of the system because newer manholes, catch basins and chambers are constructed of pre-cast concrete components. Well-installed VCP and brick pipe can provide a long trouble-free service life if left undisturbed, however factors that can weaken and disturb the pipes include masonry joint deterioration due to sewer gas, loss of supporting soil around pipe due to leakage, break-in service connections, utility construction, heavy traffic loads, and pipe cleaning procedures.

Reviews of blockage complaints and responses indicate that sewer blockages are scattered around the City, but certain problem locations are identified at times through the O&M procedures. These locations are addressed by regular sewer jetting and cleaning operations and sewer inspections and replacements where required.

A sewer inspection and rehabilitation program involving older collector sewers was performed between 1997 and 2005 to remove sags, replace broken and collapsing pipe and manholes, and stabilize cracked and fractured pipe with trenchless methods. Under the program, approximately 54,000 linear feet of the sewers were inspected and rehabilitation work included: Fold and Form polyvinylchloride (PVC) pipe lining from manhole to manhole; full length and spot lining with cured-in-place-pipe (CIPP) liners; full length and spot excavation and replacement of deteriorated pipe with new PVC pipe; and replacement of deteriorated brick manholes with new precast concrete structures.

Approximately 20% of the estimated brick sewers in the system were investigated in 2009, but this investigation concentrated on the larger brick sewers associated with the Westerly Interceptor. Other brick sewers, including smaller branch and trunk sewers, and brick manholes are considered priority assets for further assessment and rehabilitation.

2.11.2 Easterly Interceptor

A multi-sensor inspection (including sonar imaging, laser scanning, and high definition closed-circuit television recording) of the first 9,600 linear feet of the Easterly Interceptor upstream of TAPS was conducted in 2016 to assess structural and hydraulic conditions. It was determined that there may be some areas with hydrogen sulfide corrosion that may require rehabilitation in the future to arrest further deterioration. The inspection also indicated that this section of the Easterly Interceptor has heavy sediment buildup similar to the Westerly Interceptor and accumulated plastic bottles in the downstream reaches. Based on information available, there appears to be no other known structural or capacity issues requiring immediate attention.

2.11.3 Westerly Interceptor

Many sections of the Westerly Interceptor consist of brick sewers that were previously stabilized with CIPP lining or gunite coating performed circa 1987 under Contract 17 and by other

rehabilitation work performed in the late 1990s and early 2000s. These rehabilitated brick sewers were reassessed in 2008 with the conclusion that the sewers are in satisfactory structural condition. This work included the inspection and condition assessment of approximately 21,300 linear feet of brick masonry sewers (rehabilitated and unrehabilitated), which corresponds to about 20% of the brick sewers in the overall system.

Conveyance capacity to accommodate development in the Midtown Redevelopment Area was a concern in 2006 due to observed high flow levels in the Westerly Interceptor. Field work was performed to clean and inspect a 48" diameter main section and the Pearl Street, Rahway Avenue, and Cherry Street branches of the Westerly Interceptor. The cleaning work significantly reduced flow levels, but the inspections and surveys indicated some capacity concerns due to hydraulic issues existing between Rahway Avenue and Clarkson Avenue. Dry weather flow capacity modeling was performed in 2007 and determined that there were certain portions of the Westerly Interceptor where there may only be adequate capacity to accommodate existing dry weather flow. Projects are being considered to replace portions of the Westerly Interceptor in Elizabeth Avenue, Bridge Street, and South Pearl Street, including adding a siphon barrel for the Bridge Street siphon. This work is pending and future coordination with the CSO Long Term Control Plan development will be necessary.

In 2015, the 2,000 feet of 60" diameter RCP immediately upstream of TAPS to Clarkson Avenue and Britton Street was cleaned and inspected. This portion of the Westerly Interceptor was filled with approximately 12" to 18" of sediment and debris. The inspection revealed that the RCP, installed in 1958, was in very good structural and hydraulic condition, with only minimal infiltration observed. It appears that due to required operations at TAPS to minimize wet weather pumping, this section of the interceptor will have a tendency to collect sediment and debris.

2.11.4 Trenton Avenue Pumping Station

Much of the mechanical equipment, electrical gear, and building systems at the Trenton Avenue is approaching the end of their respective useful life and a major overhaul of the pump station will likely be required in the near term. The City has been working with the sewer system contract operator to make necessary equipment replacements and repairs to maintain the station operations and performance while the future upgrade for TAPS is coordinated with the CSO Long Term Control Plan development. Recent improvements implemented at TAPS include the replacement of the station's discharge flow meter, installation of new variable speed drives, control system modifications, and replacement of discharge check valves.

Operating procedures at TAPS are intended to convey as much wet weather flow to the JMEUC WWTP as allowed, but these procedures tend to contribute to the deposition of sediment and debris in the incoming interceptor sewers. Screenings from the vertical bar screens are routed through a grinder and reintroduced into the flow for pumping downstream. Screening are currently not removed for disposal at the Trenton Avenue PS. The vertical bar screens were examined by the manufacturer's field service representative in 2015 and the equipment was found to be operating full cycle and raking the screen to the bottom of the influent channel. The manufacturer's representative made minor adjustments and bent bars were straightened as per recommendations.

2.11.5 Other Facilities

Per the sewer system operator reports, no significant issues with the other pumping stations are noted. At Kapkowski Road Pumping Station, a recently installed influent sewage grinder has reduced rag related pump maintenance. The West Jersey Street Pumping Station currently

requires additional maintenance due to debris clogging, but this is anticipated to be rectified in the near term by developer-funded system improvements. A full overhaul of the South Street Stormwater Pumping Station is scheduled for the near term.

All siphons require regular maintenance including thorough cleanings. Bottles, floatables and grease tend to accumulate in the influent chambers and sediment and debris can clog the siphon barrels. The presence of bricks at the siphon chamber is another significant concern that may indicate failing upstream sewer mains or manholes. The cleanout pipes at certain siphons chambers are reported to require replacement.

The sewer system operator advises that there are no known problems with the CSO regulator / diversion structures.

There have been recurring challenges in opening and closing the large access hatches to remove and replace the netting baskets at the CSO S/F Control Facilities. Recent hatch repairs and improvements to the spring assist mechanisms have allowed easier access for routine maintenance and net replacement. No other issues are reported.

2.12 Infiltration and Inflow Analysis

N.J.A.C. 7:14A-1 defines non-excessive infiltration for separate sewer systems as the quantity of flow which is less than 120 gallons per capita per day (gpcd) (domestic base flow and infiltration), while non-excessive inflow is defined as the maximum total flow rate during storm events which does not result in chronic operational problems related to hydraulic overloading of the treatment works, such as surcharging, backups, bypasses, and overflows, or which does not result in a total flow of more than 275 gallons per capita per day (domestic base flow plus infiltration plus inflow) during a significant rainfall event which causes surface ponding and surface runoff. The regulations further define excessive inflow/infiltration as the quantities of infiltration/inflow (I/I) which can be economically eliminated from a sewer system as determined in a cost effectiveness analysis that compares the cost for correcting the I/I conditions to the total costs for transportation and treatment of the I/I.

For domestic treatment works receiving wastewater from combined sewers, the regulations note non-excessive infiltration as meaning the quantity of flow attributable to infiltration during dry weather that is less than 40 gallons per capita per day or 1,500 gallons per day per inch diameter per mile of sewer. As the collection of stormwater runoff is inherent to a combined sewer, excessive inflow restrictions are not applicable to combined sewers. In the City, CSO outfalls and control facilities that may be impacted by tidal inflow are protected by tide gates, with the tide gates located at the solids/floatables control facilities, regulator chambers, or both. Certain outfalls are also furnished with tide gates at the outfall discharge.

Data from the current combined sewer system flow monitoring program was examined to estimate the aggregate infiltration flow during dry weather and compared to the noted threshold criteria. Based on a population of 128,640 persons, the upper limit for non-excessive flow attributable to infiltration during dry weather for the City equals approximately 5.14 million gallons per day. As documented in Section 5 on the collection system modeling, the infiltration rate in the overall system is estimated to be well below this threshold, and is therefore defined as non-excessive.

Nonetheless, previous infiltration investigations conducted by the City resulted in various sewer rehabilitation projects aimed at reducing infiltration in specific areas by sealing leaking joints and other defects and replacing or rehabilitating deteriorated sewer mains and manholes. Select projects and work performed include:

- Contract 23, 23A, and 23B, completed 2004:
 - Excavation and replacement of 41 sewer reaches, totaling about 3,830 feet.
 - Excavation and partial replacement of 27 spot repairs, totaling about 1,242 feet.
 - Cured-In-Place-Pipe (CIPP) lining of 6 sewer reaches, totaling approximately 740 feet.
 - Spot repairs with CIPP lining in 17 reaches, totaling approximately 20 feet.
 - Replacement of 14 manholes.
 - Rehabilitation at 27 manholes.
- E'Town Services Mid-Town Sewer Inspection and Rehabilitation Project
 - Excavation and partial replacement of 1 spot repair, totaling about 45 feet.
 - Installation of 6 CIPP spot liners, totaling 24 feet.
 - Grouting of 17 observed pipe defects
 - Rehabilitation work (grouting and patching of defects) in 6 manholes
- Midtown Infrastructure Improvements Project, completed 2014:
 - CIPP lining of about 2,260 feet of sewer: 1,485 feet of 12" pipe, 220 feet of 15" pipe, and 555 feet of 20" diameter.
 - Reconditioned 29 manholes with grouting, patching and spray epoxy coating.
- Public Service Gas & Electric (PSE&G) Underground Transmission Line Construction, completed 2017:
 - CIPP lining of about 74 sewer reaches, totaling approximately 9,800 feet, including associated spot sewer and manhole replacements and repairs.

Furthermore, the City annually conducts over 50 repairs to sewer mains, manholes, inlets, catch basins, and outfall control facilities based on sewer cleaning and inspections and complaint responses. These annual repairs include sewer segment (manhole-to-manhole) replacements and lining work, at an average cost of approximately \$3.5 million per year.

2.13 Previous Projects for Alternatives Analysis Credit Consideration

Since the National CSO Control Policy was issued by the USEPA, the City of Elizabeth has made extensive investments in its combined sewer system for CSO abatement, CSO elimination, and stormwater drainage improvements. Many of these prior projects fall within the categories of CSO control alternatives specified in the current NJPDES CSO Permit for evaluation and potential selection in the LTCP. As the NJDEP has represented in the previous and current permit cycles, consideration of prior CSO removal and reduction projects will be incorporated in the analysis of alternatives for satisfying certain of the presumptive conditions regarding the water quality-based requirements stipulated in the permit.

Table 2-18 lists the projects completed since 2004 that the City proposes for potential consideration with the presumptive condition for CSO volume reduction and the financial affordability analysis under the alternatives evaluation stage of the LTCP development process. For each project, the table indicates the CSO control alternatives category that applies, the areas removed with sewer separation and the construction costs. As shown in the table, over \$44 million has been invested in these projects, with over 10 projects involving sewer separation that eliminated about 185 acres from contributing to combined sewer overflows.

Table 2-18: Prior Projects for LTCP CSO Control Alternatives Evaluation

Line No.	Year	Project Name	Construction Cost	Area Removed (acres)	Sewer Separation	Green Infrastructure	Increase Collection System Storage	STP Expansion	I & I Reduction	Treatment of CSO Discharge	CSO Secondary Treatment By-Pass
1	2004	Contract 2000-1 Outfall 024 and 025 Elimination	\$ 400,000	12.0	X						
2	2005	Salem Road Sewer Separation	\$ 100,000	7.0	X						
3	2007	Harding Road Combined Sewer Improvements	\$ 1,318,000				X				
4	2009	Summer Street Storm Drainage System Improvements	\$ 640,000	8.0	X

3 Hydraulic Monitoring

3.1 Background

To accurately characterize the hydrologic and hydraulic performance of the combined sewer system using an integrated catchment hydraulic computer model such as the Infoworks® ICM software, it is essential to gather precipitation and pipe flow data under existing conditions and then evaluate the performance of the hydraulic model against the observed data. A Sewer System Characterization Work Plan: Quality Assurance Project Plan (QAPP) establishing the monitoring procedures and protocols for this project was prepared and submitted to the NJDEP per the NJPDES CSO permit requirements. Furthermore, the proposed hydraulic monitoring program was presented and reviewed with the NJDEP at meetings in June and July 2015 so that an agreement was established so that commitments could be obtained from the metering subcontractor and an early start to the monitoring program initiated.

As agreed and documented in the QAPP, a precipitation and flow monitoring program was conducted from August 22, 2015 through December 21, 2015. On behalf of the City, Mott MacDonald contracted ADS Environmental Services (ADS), headquartered in Huntsville, AL, to install:

- Forty (40) continuous flow monitoring meters.
- Three (3) rain gauges
- Two (2) tide gauges
- Fourteen (14) tide gate contact switches and
- Two (2) groundwater level monitors across the system and conduct the flow monitoring process.

The locations of monitoring devices are illustrated on Figure 3-1. The complete ADS flow monitoring report dated June 2016 is included in Appendix K.

ADS performed the necessary site investigations and in conjunction with Mott MacDonald adjusted meter locations as site conditions required. The flow meters recorded the flow depth, velocity, and flow data in 5-minute intervals throughout the 4-month monitoring period. The data collected from this program was used as the basis of the hydraulic model calibration and validation. Throughout the flow monitoring program, Mott MacDonald worked closely with ADS to verify that all QA/QC procedures are strictly adhered to. Final data was extracted in Microsoft® Excel format with the 5-minute measurements appended with date/time in military format (Month/Day/Year Hour: Minute).

Out of the forty (40) installed flow meters, fourteen (14) meters were installed in dry weather flow lines that eventually connect to the interceptors, ten (10) on overflow outfall lines, six (6) each on the Easterly and Westerly Interceptors, and four (4) on storm sewer lines. Figure 3-1 shows the various monitoring locations across the City. Detailed explanation for each monitoring type is included in the succeeding sections.

3.2 Rainfall Monitoring

Three (3) rain gauges were installed in the City at the following locations:

- Gauge 1 (RG1) was installed at the Trenton Ave Pump Station located at 523 Trenton Avenue.
- Gauge 2 (RG2) was installed at the Sampson Senior Center located at 800 Anna Street.
- Gauge 3 (RG3) was installed at O'Donnell Dempsey Senior Center located at 622 Salem Ave.

These locations were in part determined by suitable facilities owned by the City for mounting rain gauges. It is important to have a well-defined and covered rain gauge network to best characterize intense and spatially variable storm events within the overall sewershed. According to the CSO Pollution Abatement Manual of Practice (WPCF, 1989), the spatial size of a typical high intensity summer storm is approximately 1.8 to 2.5 miles in diameter. The spacing defined for the three gauges provides adequate coverage to identify, characterize, and capture such spatial variations.

The rain gauges were TB6 or NovaLynx tipping buckets connected to ADS FlowShark monitors. The operation of a tipping bucket rain gauge is such that rainfall enters the funnel collector and is directed to the tipping bucket assembly. When an incremental amount of precipitation has been collected (i.e., 0.01 inches of rainfall), the bucket assembly tips and activates a switch that discharges the sample through the base of the gauge and records the tipping event, and the process is repeated. These units were installed on flat roofed, public buildings free from surrounding trees or other obstructions. The gauges were battery operated and calibrated to measure data at 5-minute intervals. Each gauge was fitted with an integral wireless telemetry unit such that data was downloaded on a predetermined schedule and interrogated on-demand when required.

At the end of the monitoring period, a total of ten (10) measurable storm events were identified, as identified below.

- 9/9/2015
- 9/10/2015
- 9/29/2015 – 9/30/2015
- 10/2/2015 – 10/3/2015
- 10/9/2015
- 10/28/2015 – 10/29/2015
- 11/10/2015 – 11/11/2015
- 11/19/2015 – 11/20/2015
- 12/1/2015 – 12/2/2015
- 12/17/2015

Table 3-1 summarizes the total measured rainfall depths for these days as recorded by the rain gauges RG1, RG2 and RG3. Individual rainfall hyetographs are included in Appendix F. As can be seen in Table 3-1, there was generally good agreement on the total rainfall volumes across the three rain gauges.

Table 3-1: Daily Rainfall Totals for the Days with Measured Rainfall

Date	Storm #	RG1 (in)	RG2 (in)	RG3 (in)
9/9/2015	#1	0.22	0.03	0.09

Date	Storm #	RG1 (in)	RG2 (in)	RG3 (in)
9/10/2015	#2	0.89	1.17	0.94
9/29/2015	#3	0.2	0.19	0.22
9/30/2015	#3	1.23	1.22	1.18
10/2/2015	#4	1.48	1.45	1.63

Source: ADS Environmental Services, Sewer Monitoring Report, June 2016.

3.3 Groundwater Monitoring

Two (2) groundwater gauges were installed in the City at the following locations:

- Groundwater Monitoring Gauge 1 was installed at Front Street and Livingston Street.
- Groundwater Monitoring Gauge 2 was located at Front Street and Elizabeth Avenue.

ADS installed piezometer tubes and pressure depth sensors to record groundwater depth. The purpose of the groundwater monitoring was to identify potential for groundwater infiltration in the City's waterfront area. These gauges were installed along the Arthur Kill as this is a low-lying region and the collection sewers in the area are VCP which have the potential to crack and allow groundwater infiltration. Thus, this was a relevant area to monitor groundwater.

Each groundwater gauge consisted of an installed conduit through a manhole wall near the bench into the ground around the manhole, of sufficient diameter to accommodate a pressure depth sensor. Each gauge was fitted with a clear flexible tube, 0.75 to 1 inch in diameter. The tube was secured to the manhole steps and extended to a point 6 inches below the manhole lid. The connection through the manhole wall consisted of a drilled hole no larger than 0.25 inches in diameter, through which a PVC or metal pipe was extended approximately 6 inches outside the manhole and into the ground. Groundwater elevation data was recorded in 60-minute intervals.

At the end of the monitoring period, the groundwater gauges did not record any measurable groundwater data at these two locations.

3.4 Tide Monitoring

Two (2) tide gauges were installed in the City at the following locations:

- Tide Gauge 1 was installed at the Elizabeth Municipal Marina in the Arthur Kill.
- Tide Gauge 2 was installed at Bridge Street in the Elizabeth River.

Tide Gauge 1 was located at the Elizabeth Municipal Marina on the Arthur Kill and gauge recording were taken as representative of Newark Bay as well. Tide Gauge 2 was located on the Elizabeth River slightly downstream of the head of tide. Each tide gauge consisted of an

installed vertical conduit (stilling well), of sufficient diameter to accommodate a pressure depth sensor. The conduit was attached to the wall of a secure waterway structure. The pressure sensor was located below the low tide elevation and connected to an ADS FlowShark monitor to record and log the tide elevation information. The data was collected and reviewed at least weekly by the ADS Data Management team via wireless communication from the office. Tide elevation was recorded at 5-minute intervals.

A check was performed on the measured tide data to confirm its validity. The following tidal datums were calculated with the measured data for TG1 and TG2. As can be seen in Table 3-2, the calculated tidal datums based on the measured data are in range and comparable to the NOAA values for Sandy Hook, NJ gaging station.

Table 3-2: Comparison of Computed Tidal Datums for Measured Data vs. NOAA Gauge

Datums	NOAA Sandy Hook, NJ (#8531680)	TG1	TG2
MHHW (Mean Higher High Water), Ft NAVD88	2.41	2.85	2.68
MLLW (Mean Lower Low Water), Ft NAVD88	-2.82	-2.82	-2.91
MHW (Mean High Water), Ft NAVD88	2.08	2.58	2.38
MLW (Mean Low Water), Ft NAVD88	-2.62	-2.64	-2.74
MTL (Mean Tide Level), Ft NAVD88	-0.27	-0.03	-0.18
DTL (Diurnal Tide Level), Ft NAVD88	-0.21	0.01	-0.11

Source: NOAA Tidal Datums – NOAA Sandy Hook Gauge

3.5 Tide Gate Limit Switches

Fourteen (14) tide gate position indicators (contact switches) were installed in the City at the locations indicated in Table 3-3.

Table 3-3: Location of Tide Gate Limit Switches

Limit Switch ID	Structure ID	Description/Location	Gate Size
1	Solid/Floatables Control Facility CSO-001	Netting facility off of Route 1 and 9 Ramp	60"
2	R-034A	Regulator 34A Puleo Plaza	60"
3	Solid/Floatables Control Facility CSO-034	Regulator 34A Puleo Plaza	60"
4	Solid/Floatables Control Facility CSO-032	Front Street across from Magnolia Ave	48"
5	Solid/Floatables Control Facility CSO-030	Parking Lot off Front Street across from East Jersey Street	48"
6	Solid/Floatables Control Facility CSO-027	Northwest corner of Summer Street and Elizabeth River	66"
7	Solid/Floatables Control Facility CSO-028	Southwest corner of Summer Street and Elizabeth River between river and Arnett Street	48"
8	CSO 026 Outfall	End of John Street at Elizabeth River	42"
9	Solid/Floatables Control Facility CSO-016	Next to Elizabeth River, behind Elizabeth Center Co-op off Pearl Street	36"
10	CSO 042 / Storage Module 5	Northeast corner of Bridge Street and Elizabeth River	90"
11	Solid/Floatables Control Facility CSO-031	South of Front Street across from Livingston Street	48"
12	Solid/Floatables Control Facility CSO-040	Pulaski Street west of Clifton Street	54"

Limit Switch ID	Structure ID	Description/Location	Gate Size
13	Solid/Floatables Control Facility CSO-022	South Street East of Elizabeth River	60"
14	Solid/Floatables Control Facility CSO-029	Veteran Park South of Front Street	48"

Each tide gate limit switch was attached to the tide gate at the hinge mechanism. The switch was connected to a data logger that recorded the time and duration of the limit switch closure which was set to coincide with the opening of the tide gate. The data was collected, uploaded and reviewed at least weekly via wireless communication from the ADS Environmental Services office. Tide gate limit switches were located downstream of flow meters to allow for identification of overflow periods for use in the scattergraph analysis. Tide gate limit switches were also located on select outfalls that were not metered so that a positive indication of an overflow event could be obtained and used to confirm the performance of the hydraulic model.

These limit switches were strategically located inside existing structures to assist with the determination of CSO overflows with a high tide tailwater condition, using scattergraph techniques. The On/OFF status of the limit switches were used to determine the overflow duration and volumes in the existing system. The overflow duration (T_{OF}) is calculated by determining the number of recorded flow monitor readings where the flow depths (d) were greater than the flow depths at the onset of the overflow (d_0), and multiplying by the sample period between readings, as shown in equation below.

$$T_{OF} = n \times T$$

Where:

T_{OF} = Overflow duration, minutes

n = Number of flow monitor readings where $d > d_0$

T = Sample period, minutes

The overflow volume (V_{OF}) is calculated by computing the algebraic differences of inflow and outflow rates and summing up for the overflow duration, as shown in equation below.

$$Q_{OFi} = Q_i - Q_0$$

$$V_{OFi} = OFi \times T$$

$$V_{OF} = \sum_{i=1}^n V_{OFi}$$

$$V_{OF} = \sum_{i=1}^n (Q_i - Q_0) \times T$$

Where:

Q_{OFi} = Overflow rate at time $t = i$, in gallons per minute (gpm)

Q_i = Flow rate at time $t = i$, gpm

Q_0 = Flow rate at onset of overflow, gpm

V_{OFi} = Overflow volume at time $t = i$, Gallons

T = Sample period, minutes

V_{OF} = Total overflow volume, Gallons

N = Number of flow monitor readings where $d > d_0$

It is noted that the scattergraph techniques outlined above are best applied for flow meter locations where backwater conditions are experienced prior to an overflow event. Overflow durations and volumes estimated using this method are a function of the quality and repeatability of the flow meter data on which they are based. If data are missing during portions of an overflow event, the application of this method may be compromised. The sample rate at which the data are obtained is also a factor. The accuracy of overflow duration and volume estimates increases as the sample rate of the flow meter increases.

3.6 Flow Monitoring

A total of forty (40) flow meters were installed across the City to obtain information necessary to accurately analyze the monitoring tributary areas for dry weather flow, inflow during rain events and infiltration during high groundwater periods. Thirty-eight (38) of the sites were installed on or before August 22, 2015, the remaining two (2) were installed and operational prior to September 1, 2015. It is noted that there was no rain during the period of August 22 to September 1, as illustrated earlier in Table 3-1. The flow meters were removed on December 21, 2015. Each metering site's dry weather hydraulic conditions were investigated by Mott MacDonald and ADS prior to the installation of flow meters. All meters installed were Triton+ meters. Two flow meters, M26 and M38, were installed on storm lines that subsequently flow into the combined sewer system. Flow meters M20 and M39 are associated with storm drains that do not discharge into the combined system, but monitoring was included for the purpose of flow generation and system completeness.

Table 3-4 summarizes the locations of the flow meters that were installed for this study.

Table 3-4: Flow Monitoring Locations

Meter ID	GIS Structure ID	Type	Description/ Location	Pipe Size	Pipe Material	Sediment Depth (in)
1	W-00-123	Combined-Interceptor	Westfield Avenue at Orchard Street and Magie Avenue	72"	RCP	0.00

The flow monitoring was accomplished using ultrasonic and pressure depth sensors combined with Doppler velocity sensors, at monitoring sites. The flow monitors were wireless and were monitored each week for performance. Site visits were performed for all sites to obtain required calibration data, perform required maintenance and assure proper operation. Flow meters within the system were ADS FlowShark Triton+ flow monitors. These are an area velocity flow monitor that uses both the continuity and Manning's equations to measure flow. The flow monitors measure open channel area velocity using peak Doppler velocity, pressure depth and ultrasonic depth, and were selected based on quality of data achieved. Prior to installation of all flow meters, each proposed meter site was investigated to determine if the site's hydraulic conditions are conducive for collecting accurate and repeatable flow data. In general, sites that exhibit non-turbulent flows with adequate cleansing velocities are preferred for flow meter installation. Upon locating an acceptable site for each flow meter, a calibration of the flow meter was performed typically at the inlet line to the manhole. A site measurement was then taken of the water depth at the meter sensor and compared to the meter output in the field with a connected laptop computer. A correct reading was achieved using calibration procedures before the meter is started.

ADS crews installed the flow sensors in the corresponding pipelines incoming to the monitored manholes. The data loggers were hung under the manhole lid and secured to the manhole wall with anchor bolt(s). The sensors were mounted on stainless steel rings or brackets securely tightened against the pipe walls with anchor bolts and cable ties. The monitor and the sensor cables were anchored to the manhole walls to allow ready access for maintenance and to minimize chances that debris or surcharging would cause the monitor or sensor ring to be dislodged. The antenna for wireless communication is inset in the pavement near the manhole opening and wired to the monitor via a small hole drilled through the manhole wall to the surface. Sensors were installed on adjustable mounting rings or brackets, and all cables were secured with anchor bolts and cable ties. Calibration was done by confirming depth readings using a handheld ruler in the flow.

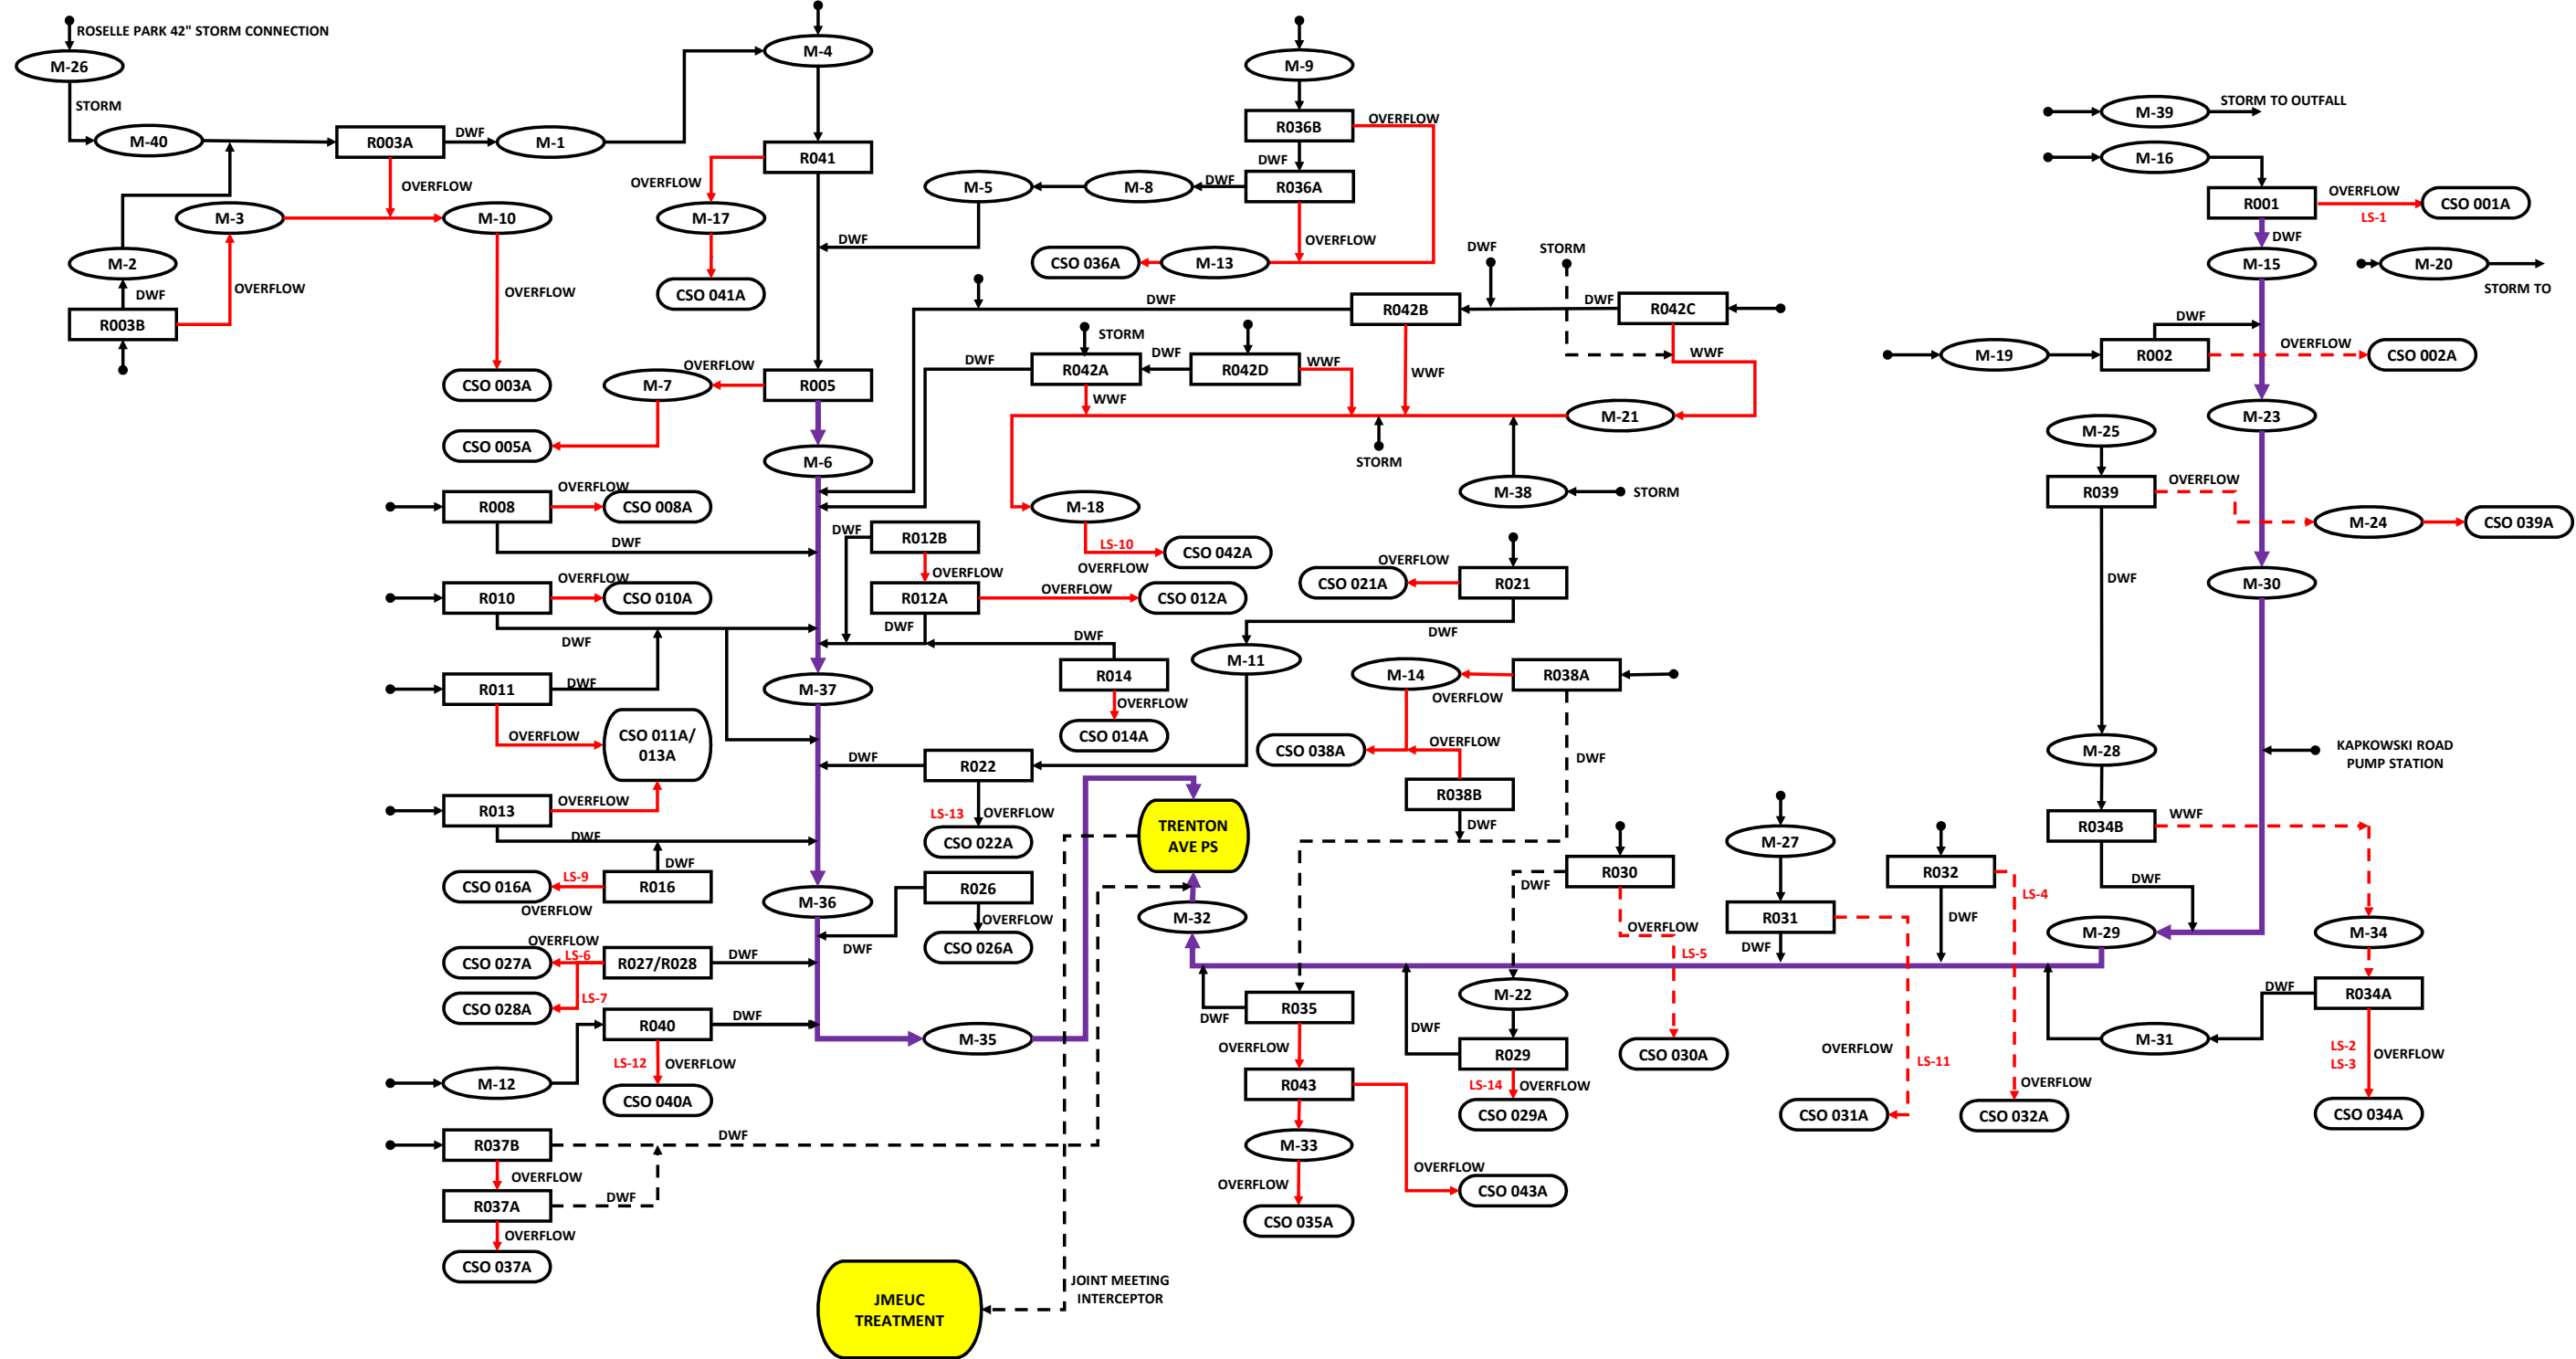

Continuous flow monitoring was conducted at the 40 locations for a period of seventeen (17) weeks to meet following conditions:

- Total precipitation volume is greater or equal to eight (8) inches (water equivalent); and
- At least two (2) small rainfall events, with precipitation, excluding contributions from snow melt, +/-0.5" of rainfall in 24 hours; and
- At least two (2) medium rainfall events, with precipitation, excluding contributions from snow melt, 0.5" to 1.5" of rainfall in a 24-hour period; and
- At least two (2) significant rainfall events, with precipitation, excluding contributions from snow melt, equal to or exceeding 1.5" of rainfall in a 24-hour period; and
- At least two high intensity events during which the hourly rainfall exceed 0.5"/hr.

A flow meter schematic detailing the flow connectivity between the meters, regulators and combined sewer outfalls is shown in Figure 3-2. A typical flow monitor hydrograph report is shown in Figure 3-3.

During the flow monitoring study, the flow depth and velocity scatter graphs for each meter were evaluated periodically to identify any anomalies in the measured data. Normal, uniform flow in a sewer typically follows the Manning's equation between the ranges of minimum and maximum pipe flows. When the metered flow depth is plotted against flow velocity, if the plot cluster closely resembles or coincides with the Manning's theoretical line, then the sewer is operating as expected. A deviation from the theoretical Manning's line can indicate the influence of a backwater or surcharge condition, flow reversal, hydraulic jump, or similar hydraulic phenomenon. A comparison of scatter graph examples is provided with Figure 3-4.

Figure 3-3: Typical Flow Monitor Hydrograph Report

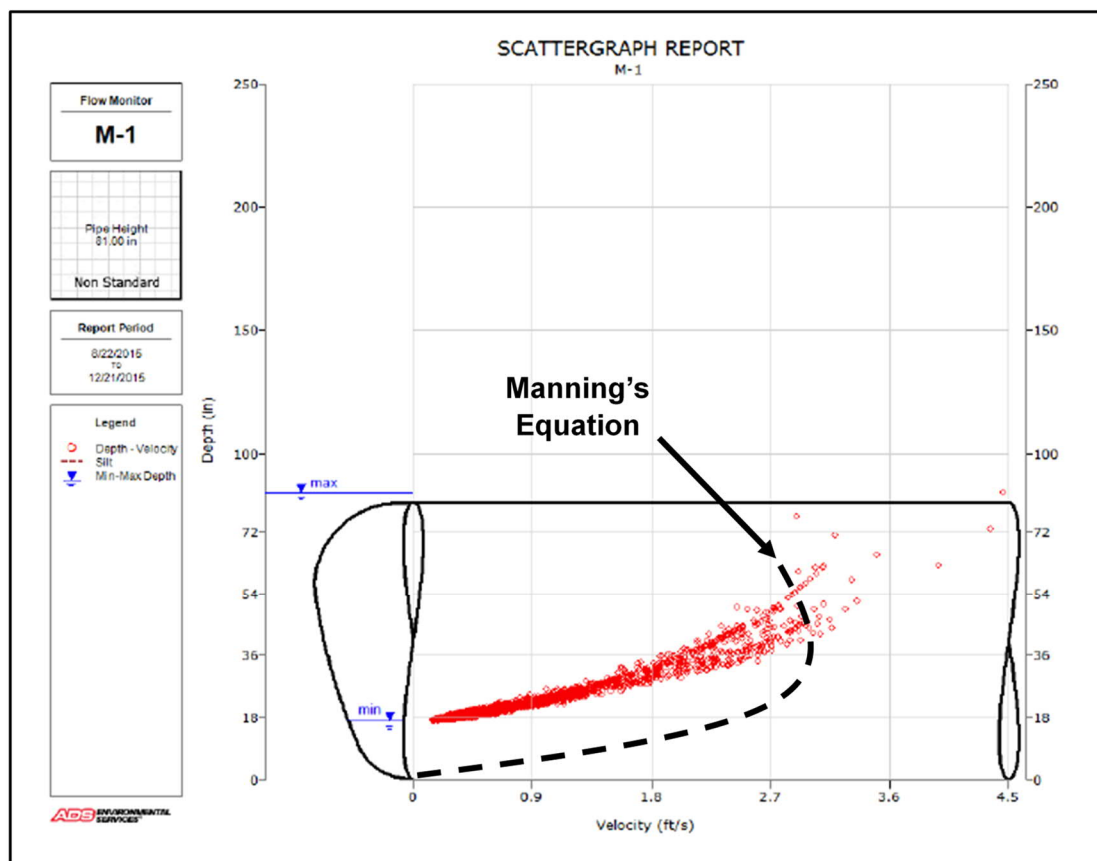

In Figure 3-4, the scatter graph for Meter M-1 is exhibiting normal and uniform flow conditions, while the scatter graph for Meter M-36 indicates a surcharge condition. M-1 is located near the headwaters of the overall collection system, M-36 is located on the Westerly Interceptor close to the Trenton Avenue Pump Station. It is known that the operation of the Trenton Avenue Pump Station as required to restrict the peak flows discharged to the JMEUC WWTP to below the contractual limit impacts the hydraulic performance and causes surcharging in both the Westerly and Easterly Interceptors. This behavior is discussed at greater depth under model calibration and validation

The one other type of scatter plot investigated was related to the combined sewer overflows. Scatter plots can be employed to disaggregate overflow and underflow volumes for tidally influenced outfalls. There are inherent difficulties in employing a velocity area meter in a tidal outfall. Since the outfall is full of water under such circumstances, the velocities tend to be low and often below the detection limit of the flow meter. Recall that fourteen (14) tide gate limit switches were installed as part of this study. These were located at the overflow lines suspected to be most tidally influence. When there is flow in an overflow line at high tide, it becomes challenging to quantify the overflow volume from the meter data since the flow meter is

expected to record all flows, including tidal ebb and flow. The tide gate limit switches were fitted to the tide gates and have a binary 0 and 1 output. When the output is 1, it signifies that the limit switch is on, the tide gate is closed and there is no tidal inflow into the system. Under this condition, an arithmetic subtraction of the flow data from the incoming meter to the outgoing meter provides an estimate of the volume of overflow. Mott MacDonald presented this technique with NJDEP and ADS Environmental at the July 9, 2015 meeting. A consensus was obtained between all parties attending the meeting regarding the use of this technique to estimate overflow volumes for CSO outfalls that area tidally influenced.

An example is shown in Figure 3-5 for flow meters M-16 and M-15 and tide gate limit switch 1. These devices were associated with the regulator for CSO Outfall 001A in the northeast corner of the City. Overflows from this area discharge into the Peripheral Ditch, which can be tidally influenced depending on tide gate conditions at the mouth of the ditch. As can be seen from the graph, the tide gate limit switch indicated a value of 1 when overflow occurred during a high tide. The flow data from M-15 (outgoing) was subtracted for that time period from the flow data for M-16 (incoming) to obtain the overflow hydrograph. And corresponding overflow volume. This is required, if the response from tide gate limit switch is not considered, it may lead to erroneous estimates of overflow volumes due to tide intrusion.

4 Wastewater Quality Monitoring

4.1 Background

A sewer flow sampling and analysis program was implemented to obtain information on dry weather and wet weather indicator bacteria concentrations so as to characterize CSO discharges and establish existing wastewater quality conditions. Per the current NJPDES CSO Permit, the wastewater characterization under this program was focused on sampling and testing for *E. coli*, fecal coliform, and enterococcus. The data collected will be used in conjunction with the baseline Compliance Monitoring Program and the pathogen water quality model of receiving waters being developed by participating members of the NJ CSO Group. This wastewater quality monitoring data is also intended to update and substantiate information collected under the past CSO discharge characterization studies and provide a basis for calculating the quality characteristics of overflows in the system.

This wastewater characterization work conforms to the "System Characterization Work Plan Quality Assurance Project Plan" (QAPP) submitted by the City to the NJDEP on December 30, 2015 as revised May 12, 2016 and per subsequent correspondence. Three (3) discrete sampling events were conducted, coinciding with significant wet weather events meeting the criteria of 0.5 inches or more precipitation occurring within a 24-hour period. Each event was preceded by a period of dry weather, defined as a minimum of three days of no precipitation following a rainfall exceeding 0.25 inches, or two days of no precipitation following a rainfall 0.25 inches or less. Table 4-1 lists the wet weather sampling date for the 3 events and the hourly precipitation occurring on the sampling date.

Source: National Weather Service, Station KEWR (Newark Liberty International Airport)

A round of dry weather sampling was conducted the day before each sampled wet weather event. Sampling crews mobilized in advance of a rainfall event and collected wet weather samples as closely as possible to the following time intervals during the event: 0.5 hour, 1 hour, 2 hours, 4 hours, and 8 hours. The wet weather sampling ended upon the collection of an 8-hour sample. All samples collected were analyzed for fecal coliform and enterococcus. Samples from 2 monitoring stations were also tested for *Escherichia coli* (E. coli) for characterizing outfall discharges to a freshwater receiving body.

Seven (7) sampling site locations were selected to obtain a representative understanding of the CSO discharge characteristics across the City. Figure 4-1 indicates the general location of the wastewater monitoring sites. A summary of the sampling station locations and the associated CSO outfall and tested parameters is given in Table 4-2.

Table 4-2: Wastewater Sampling Site Locations

4.2 Methods

Field sampling activities were performed by Mott MacDonald representatives in conformance with applicable requirements of the NJDEP “Field Sampling Procedures Manual”, revision date 2005. Grab samples for fecal coliform, enterococcus, and *E. coli* were collected directly into new sterile HDPE containers and preserved. Pre-sterilized disposable bottles were used for bacteria analyses.

Samples were analyzed for fecal coliforms, enterococcus, and *E. coli* using the analytical methods summarized in Table 4-3. The microbiological assays were conducted by Eurofins QC, Inc., a New Jersey certified analytical testing laboratory, at either the Southampton, PA or East Rutherford, NJ laboratory location. The name, address, and New Jersey Laboratory Identification Number for each location is listed in Table 4-4. A correlation of the analytical method, New Jersey Department of Environmental Protection (NJDEP) method code, and the Eurofins QC, Inc. standard operating procedure (SOP) document title is given in Table 4-3.

Table 4-3: Analytical Test Methods

Parameter	Analytical Method	NJDEP Method Code	Laboratory Standard Operating Procedure Title
Fecal coliforms	SM 9222 D-97	NPW01.00300	Membrane Filter (MF) Technique for Members of the Fecal Coliform Group
Enterococcus	EPA 1600	NPW01.00020	Membrane Filter (MF) Technique for Enterococci
<i>E. coli</i>	EPA 1603-09	NPW01.00100	<i>E. Coli</i> in Water by Membrane Filtration Using Modified Membrane-Thermotolerant <i>Escherichia coli</i> Agar (Modified mTEC)

Table 4-4: Eurofins QC, Inc. Laboratory Locations

Laboratory Name	Address / Contact	NJ Laboratory ID No.
Eurofins QC, Inc.	1205 Industrial Highway Southampton, PA 18966 tel. 215-355-3900	PA166
Eurofins QC, Inc. - East Rutherford Division	196 Paterson Avenue East Rutherford, NJ 07073 tel. 201-729-1907	02015

Wastewater samples were collected during dry and wet weather conditions. Samples from all monitoring sites were analyzed for fecal coliform and enterococcus. Samples from Site 1 (CSO Outfall 003A - Westfield Avenue) and Site 2 (CSO Outfall 022A - South Street) were also analyzed for *E. coli*. Dry weather samples were collected for each site on the day before the wet weather event. For wet weather monitoring, samples were collected at each site at 5 internal times during the event (at approximately 30 minutes, 1 hour, 2 hours, 4 hours, and 8 hours.)

The samples for laboratory analysis were preserved per laboratory methods and transferred to Eurofins QC, Inc. for analysis under standard chain-of-custody (COC) protocols. Collected samples were submitted to Eurofins QC, Inc. either to their East Rutherford, NJ location or Southampton, PA location. Samples were delivered to the laboratory within three hours of the sample being taken so that Eurofins QC, Inc. could conduct the analyses within the applicable holding times.

Staff members were trained for the field sampling work through training sessions that included an overview of the project, sampling procedures, sampling locations and access, instructions for taking a sample, completing a chain of custody form, delivering a sample, and health and safety

considerations. Field sampling activities were scheduled based on daily reviews of weather forecasts from various sources such as Accuweather, Weather Underground, Intellicast, and the National Weather Service.

Once target wet weather sampling date was identified a few days in advance, dry weather sampling was scheduled and conducted the day prior. The weather was monitored closely until the sampling date for any possible changes in direction, intensity, or duration. Sampling materials, including bottles, deionized water, latex gloves, coolers, ice, sampling buckets, and chain of custody forms were assembled in advance for each sampling event. Bottles were pre-labelled for ease of sampling and record-keeping. Eurofins QC, Inc. was notified of each upcoming sampling event in order to make the necessary arrangements for staffing and operating hours.

4.3 Results

The results of the sewer sampling program are summarized in the tables below. The analytical test reports as provided by the testing laboratory are included in Appendix C.

Table 4-5 provides a summary of the dry weather analytical results for each sampling location and Events 1, 2 and 3. Information regarding each sample, including the collection date, collection time, and the sample identification number assigned by the testing laboratory, is given. The measured concentrations for E. coli (where tested), fecal coliform, and enterococci are tabulated for the wastewater samples and for the field blank samples.

Table 4-6, Table 4-7, and Table 4-8 provide similar tabulations of the wet weather sampling and corresponding measured bacteria concentrations for Events 1, 2, and 3, respectively. The sample descriptions and the analytical results for E. coli (where tested), fecal coliform, and enterococci associated with each site, sampling period, and field blank tested under each wet weather event are noted.

In addition to the 3 events noted in the report tables, a false start event occurred on October 27, 2016, in which the sampling crews were mobilized to the monitoring sites but a prolonged delay in the predicted rainfall intensity necessitated a cancellation of the wet weather sampling.

Table 4-6 indicates that no wet weather samples were collected at Site 7 (Outfall 042A, Winfield Scott Plaza netting chamber) for the Event 1 sampling on November 29, 2016. Although the water levels in the diversion manhole at this site were monitored and rose during the wet weather event, the level did not reach the outlet to the netting chamber. A review of the sewer system record plans noted that the overflow elevation at other diversion structures in this sewershed were lower than the overflow level to the netting chamber. In subsequent wet weather events, the field crews inspected the downstream outfall discharge point associated with Site 7 and coordinated the sampling at the diversion manhole accordingly.

For wet weather sampling on April 25, 2017 under Event 2, a prolonged delay in the start of the rainfall conflicted with the hours of operation and the available staffing of the contract laboratory. Precipitation was forecasted to begin at approximately 12 pm, but did not actually start until around 4 pm. After extensive discussions with the contract laboratory, it was determined that given the limited available overnight testing capacity and that sampling staff would be in the field for over 12 hours since mobilizing that day, the last batch of samples needed to be collected at approximately midnight and delivered to Eurofins QC, Inc. laboratory in Southampton, PA. As such, the last Event 2 wet weather samples were collected at approximately 6.5 hours from the initiation of overflow, or about 1.5 hours before the targeted period of 8 hours. Nonetheless, the samples were delivered and analyzed within the required holding time. Also, a final wet weather

sample could not be collected at Site 6 for Event 2 as this sampling site is located on private property and the property owner was not able to provide the field team with access at midnight.

Qualified Data

As part of the microbiological laboratory testing performed, the methodologies approved for bacteria require preparation of appropriate sample dilutions so that the number of colonies to be counted on the plate is between 20 and 60. Due to the wide variability of bacteria concentrations in surface waters, stormwater, and sanitary sewage, it is difficult to estimate the level of dilution necessary to achieve specified plate count range. As a result, some of the concentrations reported by the testing laboratory are considered estimates because the number of colonies fell outside of the 20 to 60 range when counted. These results are given a qualifier

of “E”, described by the laboratory as “For microbiology testing by membrane filtration, the reported result was based on a colony count outside the recommended range of the test. The reported result may be considered an estimate”. E-qualified data still meet the needs for this wastewater quality characterization, with the data considered as estimates rather than exact values.

The bacteria measurements also have a specific holding time required by the laboratory methodology, which is a maximum of 8 hours. When an analysis is conducted outside of 8 hours, the concentrations are given a qualifier of “Q”, noted by the laboratory as “Microbiological testing was conducted outside of the recommended holding time of 8 hours. Results may not be acceptable for regulatory purposes.” Q-qualified data still meet the needs of this CSO discharge characterization, as the information is not being used for an assessment of compliance.

As is to be expected from such a large-scale and long-term sampling effort, Q-qualified data occurred more frequently during the initial stages of the sampling program and decreased over the course of the sampling program. Once the length of time to take samples and deliver them to the lab was established, procedures were adopted to ensure that samples would arrive at the lab with enough time to be analyzed. As such, there were seven Q-qualified data in the first sampling event, no Q-qualified data in the second sampling event, and two Q-qualified data points in the third sampling event. It is noted that two of the total nine Q-qualified field blank samples were marked as such because no sampling time was indicated on the bottles. However, field staff verified that the field blanks was taken around same time as the 30-minute sample in Event 1, so those two samples likely did not in fact exceed the 8 hour holding time. In addition, five more of the nine Q-qualified data points were analyzed within 8.5 hours of sampling, thus the data should still be viable for use in analysis.

Table 4-9 and Table 4-10 below present the number of non-qualified, E-qualified, and Q-qualified samples for the dry weather and wet weather sampling events.

Table 4-9: Counts for Qualified Data - Dry Weather Samples

4.4 Sewer Sampling Data Analysis

The average and ranges for indicator bacteria concentrations from the dry weather sewer flow analyses are presented in Table 4-11, where the geometric mean (i.e., the central tendency of a set of numbers based on the product of the values, or the nth root of the product of n numbers), the arithmetic mean, the minimum value, and the maximum value for the set of dry weather concentrations from the 3 sampling events are given for each sampling station site and analytical parameter. Geometric means are typically used for reporting bacteria concentrations to account for the naturally larger fluctuations between data points caused by the exponential growth rates of these populations. The geometric means for the dry weather E. coli, fecal coliform, and enterococci concentrations were 2.64×10^6 , 3.82×10^6 , and 0.89×10^6 cfu/100mL, respectively. The range of values shown in Table 4-11 are typical for raw wastewater flows¹ and complement the results from the 2006 Baseline Monitoring Report². The maximum fecal coliform concentration of 32×10^6 cfu/100mL measured at Site 6 is notably greater than the other data points, but it is within normal observations for wastewater. Furthermore, the values observed are consistent with the results from previous studies.

Legend and Notes:

NA = Not Applicable, sample collection and analysis not proposed.

Table 4-12 indicates the wet weather concentration averages and ranges for all sample collection times by sampling event, station site, and analytical parameter. A comparison of Table 4-11 and Table 4-12 indicates that the mean for the wet weather data is lower than the mean for the dry weather data for each parameter, which is indicative of dilution over the course of the wet weather events. A peak fecal coliform concentration of 108×10^6 cfu/100mL was measured at Site 3 during Wet Weather Event 2. The maximum wet weather fecal coliform concentration for 6 of the 7 sampling stations occurred during Event 2, which corresponded with an initiation of sampling during the late evening. Less variability is evident in the wet weather concentrations for E. coli and enterococci. The overall values and ranges are again consistent with results from 2006 Baseline Monitoring Report and with typically reported data.

¹ U.S. Environmental Protection Agency, Office of Water. *Report to Congress: Impacts and Control of CSOs and SSOs*. Washington, D.C.: Office of Water Resource Center, August 2004. (EPA 833-R-04-001)

² Hatch Mott MacDonald. *City of Elizabeth (Union County, NJ) Combined Sewer Overflow Discharge Characterization Study: Baseline Monitoring Report*. May 2006.

Table 4-13, Table 4-14, and Table 4-15 give the wet weather concentration averages and ranges utilizing the data sets from the 3 events by the sample collection period (i.e., elapsed time after the initiation of overflow sampling) and station site for *E. coli*, fecal coliform, and enterococci, respectively. Figure 4-2 provides a graphical representation of the *E. coli* analytical data on a logarithmic scale versus the sample collection time. It includes the data from the 3 wet weather events in a bar chart form against the elapsed time after the start of sampling (corresponding to the sample collection time), with a geometric mean trend line for comparison purposes. Figure 4-3, Figure 4-4, and Figure 4-5 present similar graphs for fecal coliform wet weather data for Events 1, 2, and 3 respectively, while Figure 4-6, Figure 4-7, and Figure 4-8 provide the time series graphs of the enterococci results for each respective event.

These tables and figures demonstrate the wet weather bacteria data is highly variable. There appears to be a general decrease in the indicator bacteria concentrations after 1-hour sample collection times for most events and sites, indicating a probable concentration decrease after an initial CSO activation and “first flush” period as a higher wet weather flow rate is sustained. There also appears to be a trend to slightly higher concentrations from the 4-hour samples to the 8-hour samples. This may be indicative of decreasing wet weather flow rate as the storm and overflow event ends.

A review of the wastewater quality data collected indicates that the intended goal of characterizing dry weather and wet weather bacteria concentrations within the combined sewer system has been met. Approximately 96% of targeted samples were collected and analyzed, representing a total of 278 data points for dry and wet weather bacteria concentrations, including values as an overflow event occurs. This data is appropriate and suitable for representing the indicator bacteria concentrations in existing combined sewer system dry weather flows and wet weather overflow discharges.

5 Collection System Modeling

5.1 Background

The goal of the combined sewer system (CSS) modeling process is to create a model that accurately reflects the combined sewer system's response to conveying flows and provides a solid basis for making future system improvements and modifications. To understand the existing operation of the combined sewer system and the impacts of future projects, Mott MacDonald developed a computer model of the City's combined sewer system that can serve as a tool to evaluate the "baseline" conditions in the network and to evaluate alternatives. The hydraulic model was developed using the Innovyze InfoWorks® ICM computer program that is based on EPA SWMM to compute runoff generation and collection system hydraulics. Like SWMM, ICM is a distributed and dynamic rainfall-runoff simulation model that can be used for single event or long-term (continuous) simulation of runoff quantity and quality. ICM is capable of simulating 1D flow in conveyance links and 2D overland flows and runoff flows in drainage systems, components of which can be represented by using a combination of nodes, links, mesh elements, weirs, orifices etc. objects available in the program. ICM provides the capability to simulate backwater effects, flow reversals, surcharging, looped connections, pressure flows, tidal outfalls, and interconnected ponds by using the full dynamic wave (hydrodynamic) flow routing option. The dynamic wave algorithms solve the one-dimensional unsteady state St. Venant's continuity and momentum equations to produce theoretically accurate results for a drainage scenario.

Two types of flow inputs are necessary for combined sewer models, namely, storm and sanitary flows. Sanitary flows are typically calculated based on population or land use such as industrial and commercial. Storm flow inputs to the network objects is performed by using sub-catchments. Each sub-catchment can be characterized by two different types of surface, pervious and impervious, that have unique flow generation characteristics. Pervious surfaces are considered to infiltrate portion of the rainfall based on empirical equations (e.g. Horton Equation). The basic premise of such equations is that the portion of the rainfall infiltrated can be estimated based on the characteristics of the underlying soil. Rainfall will continue to infiltrate as long as the intensity of rain is less than the soil absorption capacity. More intense and/or prolonged rainfalls will produce surface runoff which will enter the downstream collection system. Impervious surfaces (e.g. buildings, paved roads) in an urban environment such as the City are considered as Directly Connected Impervious Areas (DCIA) that aside from a small amount of initial losses from depression storage, a major portion of the rainfall will result in runoff.

Each of these items are discussed in greater detail throughout the remainder of this report, along with supporting calculations.

5.2 Model Development

5.2.1 Sewershed Delineation

A detailed delineation of influent sewersheds was performed using all available data. Surface runoff flow patterns were identified using Digital Elevation Model (DEM) data that is available through the US Geological Survey National Elevation Dataset. The GIS dataset of the combined sewer system was used in tandem with the DEM data to identify sewershed divides, flow input points and influent areas to the system.

The total sewershed area that contributes combined sewer flows into the system is approximately 4,681 acres (7.3 sq. miles). This is made of approximately 3,420 acres (5.3 sq. miles) of combined areas (both storm and sanitary input), 1,085 acres (1.7 sq. miles) of separate sanitary areas (storm is separate and connects elsewhere), and 176 acres (0.3 sq. miles) of separate storm areas (no sanitary). It is noted that out of the 176 acres of separate storm areas, approximately 112 acres is attributed to a storm shed situated in the Borough of Roselle Park (located northwest of the City) that contributes storm inflows into the City's combined sewer system. The distribution of contributing sewersheds by type are shown in Figure 5-1.

Figure 5-1: Types of Influent Sewersheds to the Elizabeth System

The entire study area was divided into a total of six hundred and ninety-four (694) sewersheds. Certain areas of the City have sanitary flows that connect to either the Easterly or Westerly Interceptor, while the storm flows into separate sewers that ultimately outfall into surface water bodies. The average size of all sewersheds delineated was approximately 6.7 acres. The goal was to strategically divide the sewersheds so that the model can be used to zoom into and evaluate hydraulic characteristics of smaller areas efficiently.

To account for such separate sewer areas, twenty-three (23) individual sewersheds were duplicated in Infoworks ICM to have separate flow generation characteristics for sanitary and storm inputs, into different areas of the overall combined sewer system. A map of the delineated sewersheds is included in Appendix A of this report.

5.2.2 Model Geometry

Model geometry comprises of structures, manholes, pipes, regulators, pump stations etc. that can regulate and/or impact flows in a sewer system. ICM has a GIS interface to import/export GIS data that has powerful tools to aid in model construction. The Citywide GIS dataset of the combined sewer network was imported into ICM for model development. The manholes were coded in as node objects, while the pipes were coded in as links that connects to multiple nodes. No inlets were included in the model geometry development; existing inlet locations were used to delineate sewersheds that were used as flow inputs to the ICM model. To keep

the number of pipes in ICM model reasonable, pipe sizes smaller than 12 inches were excluded, except when smaller pipes were identified to be located along the trunk interceptor lines, at flow control structures or outfalls, or were otherwise necessary to maintain flow continuity. This is a reasonable approach, inclusion of too many small pipes in a model dramatically increases model run times and impacts model stability while not appreciably improving the model's ability to better predict real world conditions. Figure 5-2 shows the breakdown of the entire system by pipe sizes, in GIS and Infoworks ICM. The existing combined sewer system has approximately 1.14 million linear feet (LF) of piping, out of which approximately 766,000 LF are combined sewers, 63,600 LF is sanitary, and the rest are separate storm sewers. Storm piping was excluded in Infoworks ICM. Overall, approximately 624,000 LF of piping was included in the Infoworks ICM model geometry, representing about 55% of the entire (combined, sanitary and storm) system. It is our understanding that NJDEP recommends including pipe sizes greater than or equal to 24 inches for modeling purposes. The current study provides for a more detailed hydraulic system by utilizing a pipe size cutoff of 12 inches and greater.

The majority of structure and pipe geometry data (size, material, inverts etc.) were obtained based on research of as-built drawings and supplemented with field survey, as required. There were instances when no geometry data could be obtained due to lack of access to structures. Under such circumstances, the geometry data was interpolated based on known data. ICM has a data inference feature that was utilized in such cases. ICM can infer (interpolate) missing pipe inverts based on upstream and downstream known inverts, connecting pipe slopes, or known inverts at a connecting structure with multiple pipe connections. This is a widely accepted practice, as the pipes are expected to have positive slope downstream, the missing information can be filled in with reasonable assumptions made based on known data.

Figure 5-2: Distribution of Pipe Sizes in Existing System & Hydraulic Model

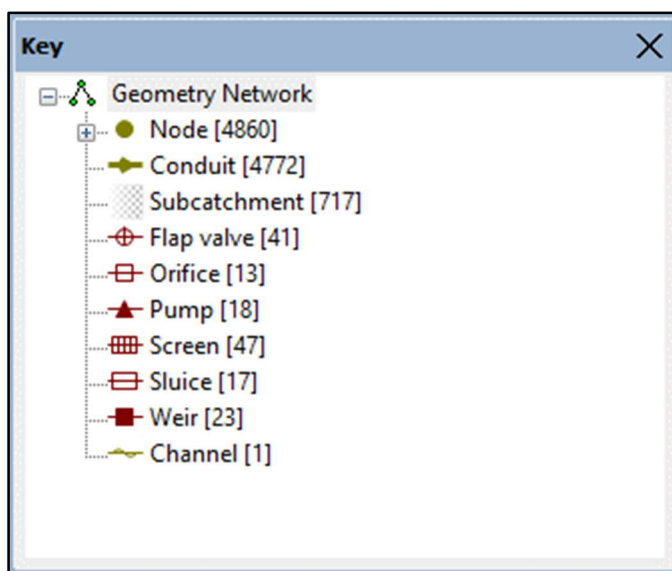

In summary, the following items were included into the ICM model from GIS data:

- All combined sewer and sanitary pipes 12" or greater.
- Sewers smaller in size than 12" when they were located either in trunk interceptor lines, on flow control structures outfall lines, or were otherwise necessary to maintain flow continuity.
- All trunk sewers tributary to the Trenton Avenue Pump Station, including the Easterly and Westerly Interceptors.
- All CSO regulators, netting chambers, inverted siphons, weirs, channels, screens, tide gates, flap gates, sluice gates, and pump stations that can impact flows in the system. It is noted that existing siphons were modeled using conveyance links (pipes) in Infoworks ICM.

Figure 5-3 summarizes the components of the geometry network in Infoworks ICM model.

Figure 5-3: Summary of Hydraulic Elements in ICM Model

5.2.3 Pipe Roughness

Hydraulic roughness, which is represented by the Manning's roughness coefficient ("n"), is a means of accounting for the effect on the resistance to flow of pipe materials, irregularities, debris, and other obstructions. Flow through pipes can incur a higher headloss depending on the roughness. As such, it is important to capture the roughness accurately in a system to properly identify the flow patterns.

Pipe roughness were assigned based on pipe materials identified during the GIS dataset development. Consideration was given to records that indicated that an existing pipe was lined as part of a previous pipe rehabilitation project. For example, lining an old and ageing brick pipe with concrete reinstates its structural integrity, reduces its roughness, increases its hydraulic capacity, and improves its hydraulic characteristics. A range of Manning's N roughness values were selected for the existing combined sewer system, based on original pipe material and pipe lining, as depicted in Table 5-1.

Table 5-1: Summary of Manning's Roughness Coefficients Used in Modeling

Pipe/ Lining Material	Label	Manning's N used in Model	Source of Manning's N
Reinforced Concrete Pipe	RCP	0.012	NJDOT Drainage Design Manual
Clay/ Terracotta Pipe	VCP	0.014	NJDOT Drainage Design Manual
Cast Iron Pipe	CI	0.013	NJDOT Drainage Design Manual, VT Chow
Brick Pipe	BRK	0.015	NJDOT Drainage Design Manual, VT chow
Asbestos Cement Pipe	AC	0.013	http://www.co.mecosta.mi.us/PDFs/Drain_Commissioner/Appendix/Appendix%205.7%20-%20Mannings%20Roughness.pdf
Ductile Iron Pipe	DI	0.013	http://www.concretepipe.org/wp-content/uploads/2014/09/DD_10.pdf
Poly Vinyl Chloride Pipe	PVC	0.011	HEC-22 AND http://www.concretepipe.org/wp-content/uploads/2014/09/DD_10.pdf
GUNITE Pipe Lining	GUNITE	0.019	VT Chow

Cured-in- Place Pipe	CIPP	0.012	Same as RCP and Concrete Pipe

Source: As indicated

Figure 5-4 shows a distribution of pipe materials across the existing network. It can be observed that major portion of the existing network comprises of vitrified clay and brick pipes, typical of old combined sewer systems.

Figure 5-4: Distribution of Pipe Materials in Existing System

5.3 Representation of Flow Control Structures in Model

Hydraulic flow control structures, such as regulators are essentially flow “splitters”, i.e., they divide the incoming flow based on the elevation of the hydraulic grade line at the upstream side of the structure. For a combined sewer system, accurate depiction of such structures is important since the hydraulic model computes system overflows based on the flow hydraulics at these structures.

Typically, regulators have internal concrete walls with low flow openings to regulate the incoming flow. Regulators that are tidally influenced typically have flap gates or backflow preventers to prevent the intrusion of high tide into the system. Hydraulically, the walls can be represented by weirs, low flow openings by orifices, and backflow preventers by flap valves; this is standard modeling practice. Under dry weather conditions, the influent low flows pass through the orifices or low flow channels into an interceptor. During wet weather conditions, as the influent flow and water level increases inside the regulator, when the water level exceeds the top (crest) of the weir, a portion of the influent flow is diverted to an outfall, creating a combined sewer overflow. Such a hydraulic arrangement is schematically depicted in the Figure 5-5.

For the purposes of hydraulic modeling, flow regulators were modeled in Infoworks ICM using weirs, orifices, flap valves and pipe conveyance links to capture the flow split in the system. One such example is shown in Figure 5-6 for existing regulator R026, the concrete weir inside the existing structure was modeled as a weir link, while the low flow was modeled as an orifice. Under dry weather flow conditions, the incoming flow passes through the orifice and the overflow line is dry. Under wet weather flow conditions, when the hydraulic grade line inside the structure is higher than the crest of the weir, a portion of the flow overtops the weir and continues to flow through the overflow line.

Figure 5-5: Typical Flow Regulator Schematic in Combined Sewer System

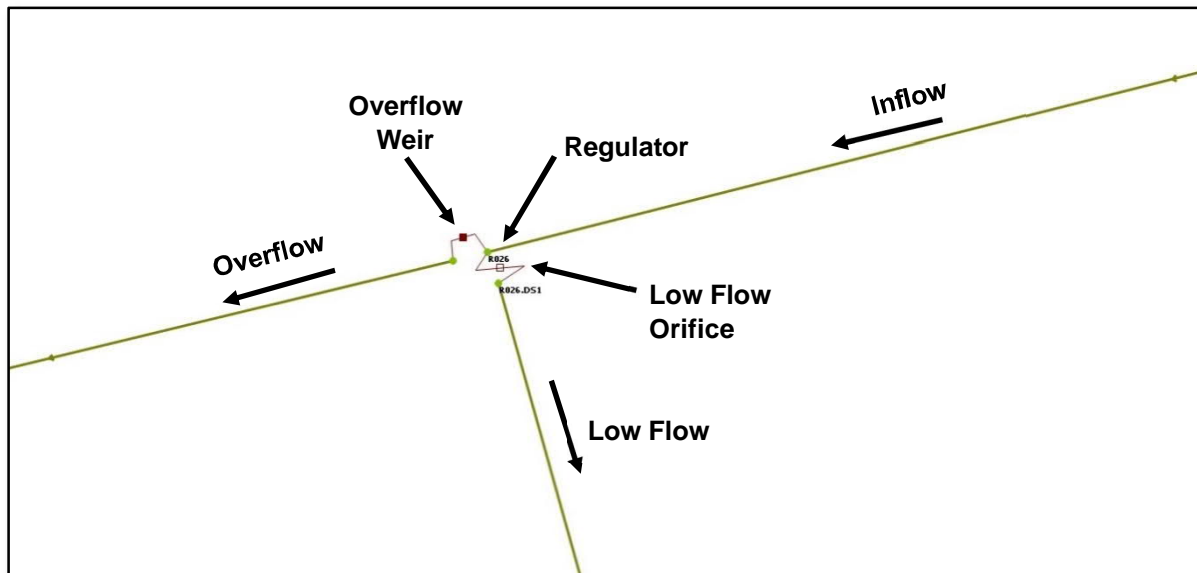

Figure 5-6: Typical Representation of Regulator Structure in Infoworks ICM Model

5.4 Rainfall Data Analysis

Precipitation is the driving force in a rainfall-runoff simulation. Stormwater runoff generated and entering the sewer system is partially or strongly dependent on the precipitation, its duration and time varying intensity, all of which may vary spatially for a storm system. Even for small sewersheds, runoff generation and consequent model predictions may be very sensitive to spatial variations of the rainfall. For instance, thunderstorms (convective rainfall) may be highly localized, and nearby rain gages may have very dissimilar readings. Given the large size of the current study area, rainfall is expected to vary spatially over this region for each rainfall event. As such, each rain gage is expected to have its “zone of influence” around its location. To account for this spatial variability, Thiessen polygons (also called Voronoi polygons) were constructed for each rain gage. Thiessen polygons define individual areas of influence around each gage point so that any location inside the polygon is closer to that point than any of the other points. Mathematically, these polygons are defined by the perpendicular bisectors of the lines connecting the points. Using Thiessen polygons to accurately quantify spatial variation is one of the widely used techniques in water resources and environmental engineering.

As indicated earlier, the total sewersheds area that contributes flows into the City’s combined sewer system (excluding areas that flow directly to the JMEUC interceptor sewers) is approximately 4,681 acres, out of which, approximately 3,420 acres is combined and 176 acres is storm that eventually connects to the combined system. Out of this subset, approximately 970 acres fall within the zone of influence of RG1, 1,020 acres under RG2, and the remaining 1,606 acres under RG3 based on the Thiessen polygon analysis. The relative location of the individual sewersheds with respect to the three rain gages and their Thiessen polygons are shown in Figure 5-7. All sewersheds within a Thiessen polygon were assigned the rainfall profile associated with the polygon. Sewersheds that fell between areas were assigned the rain gage they fell primarily in. This was considered appropriate as the sewersheds are relatively small and would not impact overall results at the flow meter locations.

Use of other methods such as radar rainfall data or construction of isohyets were considered in the study. Radar rainfall typically have a 2.5 sq. mile grid, with rainfall data only available in 1-hour increments. As such, use of data from the three rain gages provides larger level of detail compared to radar data. Isohyets can be created by using rainfall data from RG1, RG2, and RG3. However, the bounds of the isohyets will be limited to the triangle created by connecting the rain gage locations. Such a setup will provide detailed rainfall data for sewersheds that fall within the triangle, and no data for ones that will fall outside. As such, the use of Thiessen polygons was deemed the most appropriate and effective means to account for spatial variation of rainfall across the entire study area.

In addition, to isolate the total duration of each rain storm, the longest duration of contiguous rainfall (without any gaps exceeding six hours) was identified. Table 5-2 summarizes the start and end times of contiguous rainfall that were identified from the measured rainfall data. To further classify the rainfall data, the maximum 1-hour intensity was also determined for each rainfall event, as indicated in Table 5-2. Figure 5-8 shows the computed maximum 1-hour rainfall intensities for the measured rainfall events.

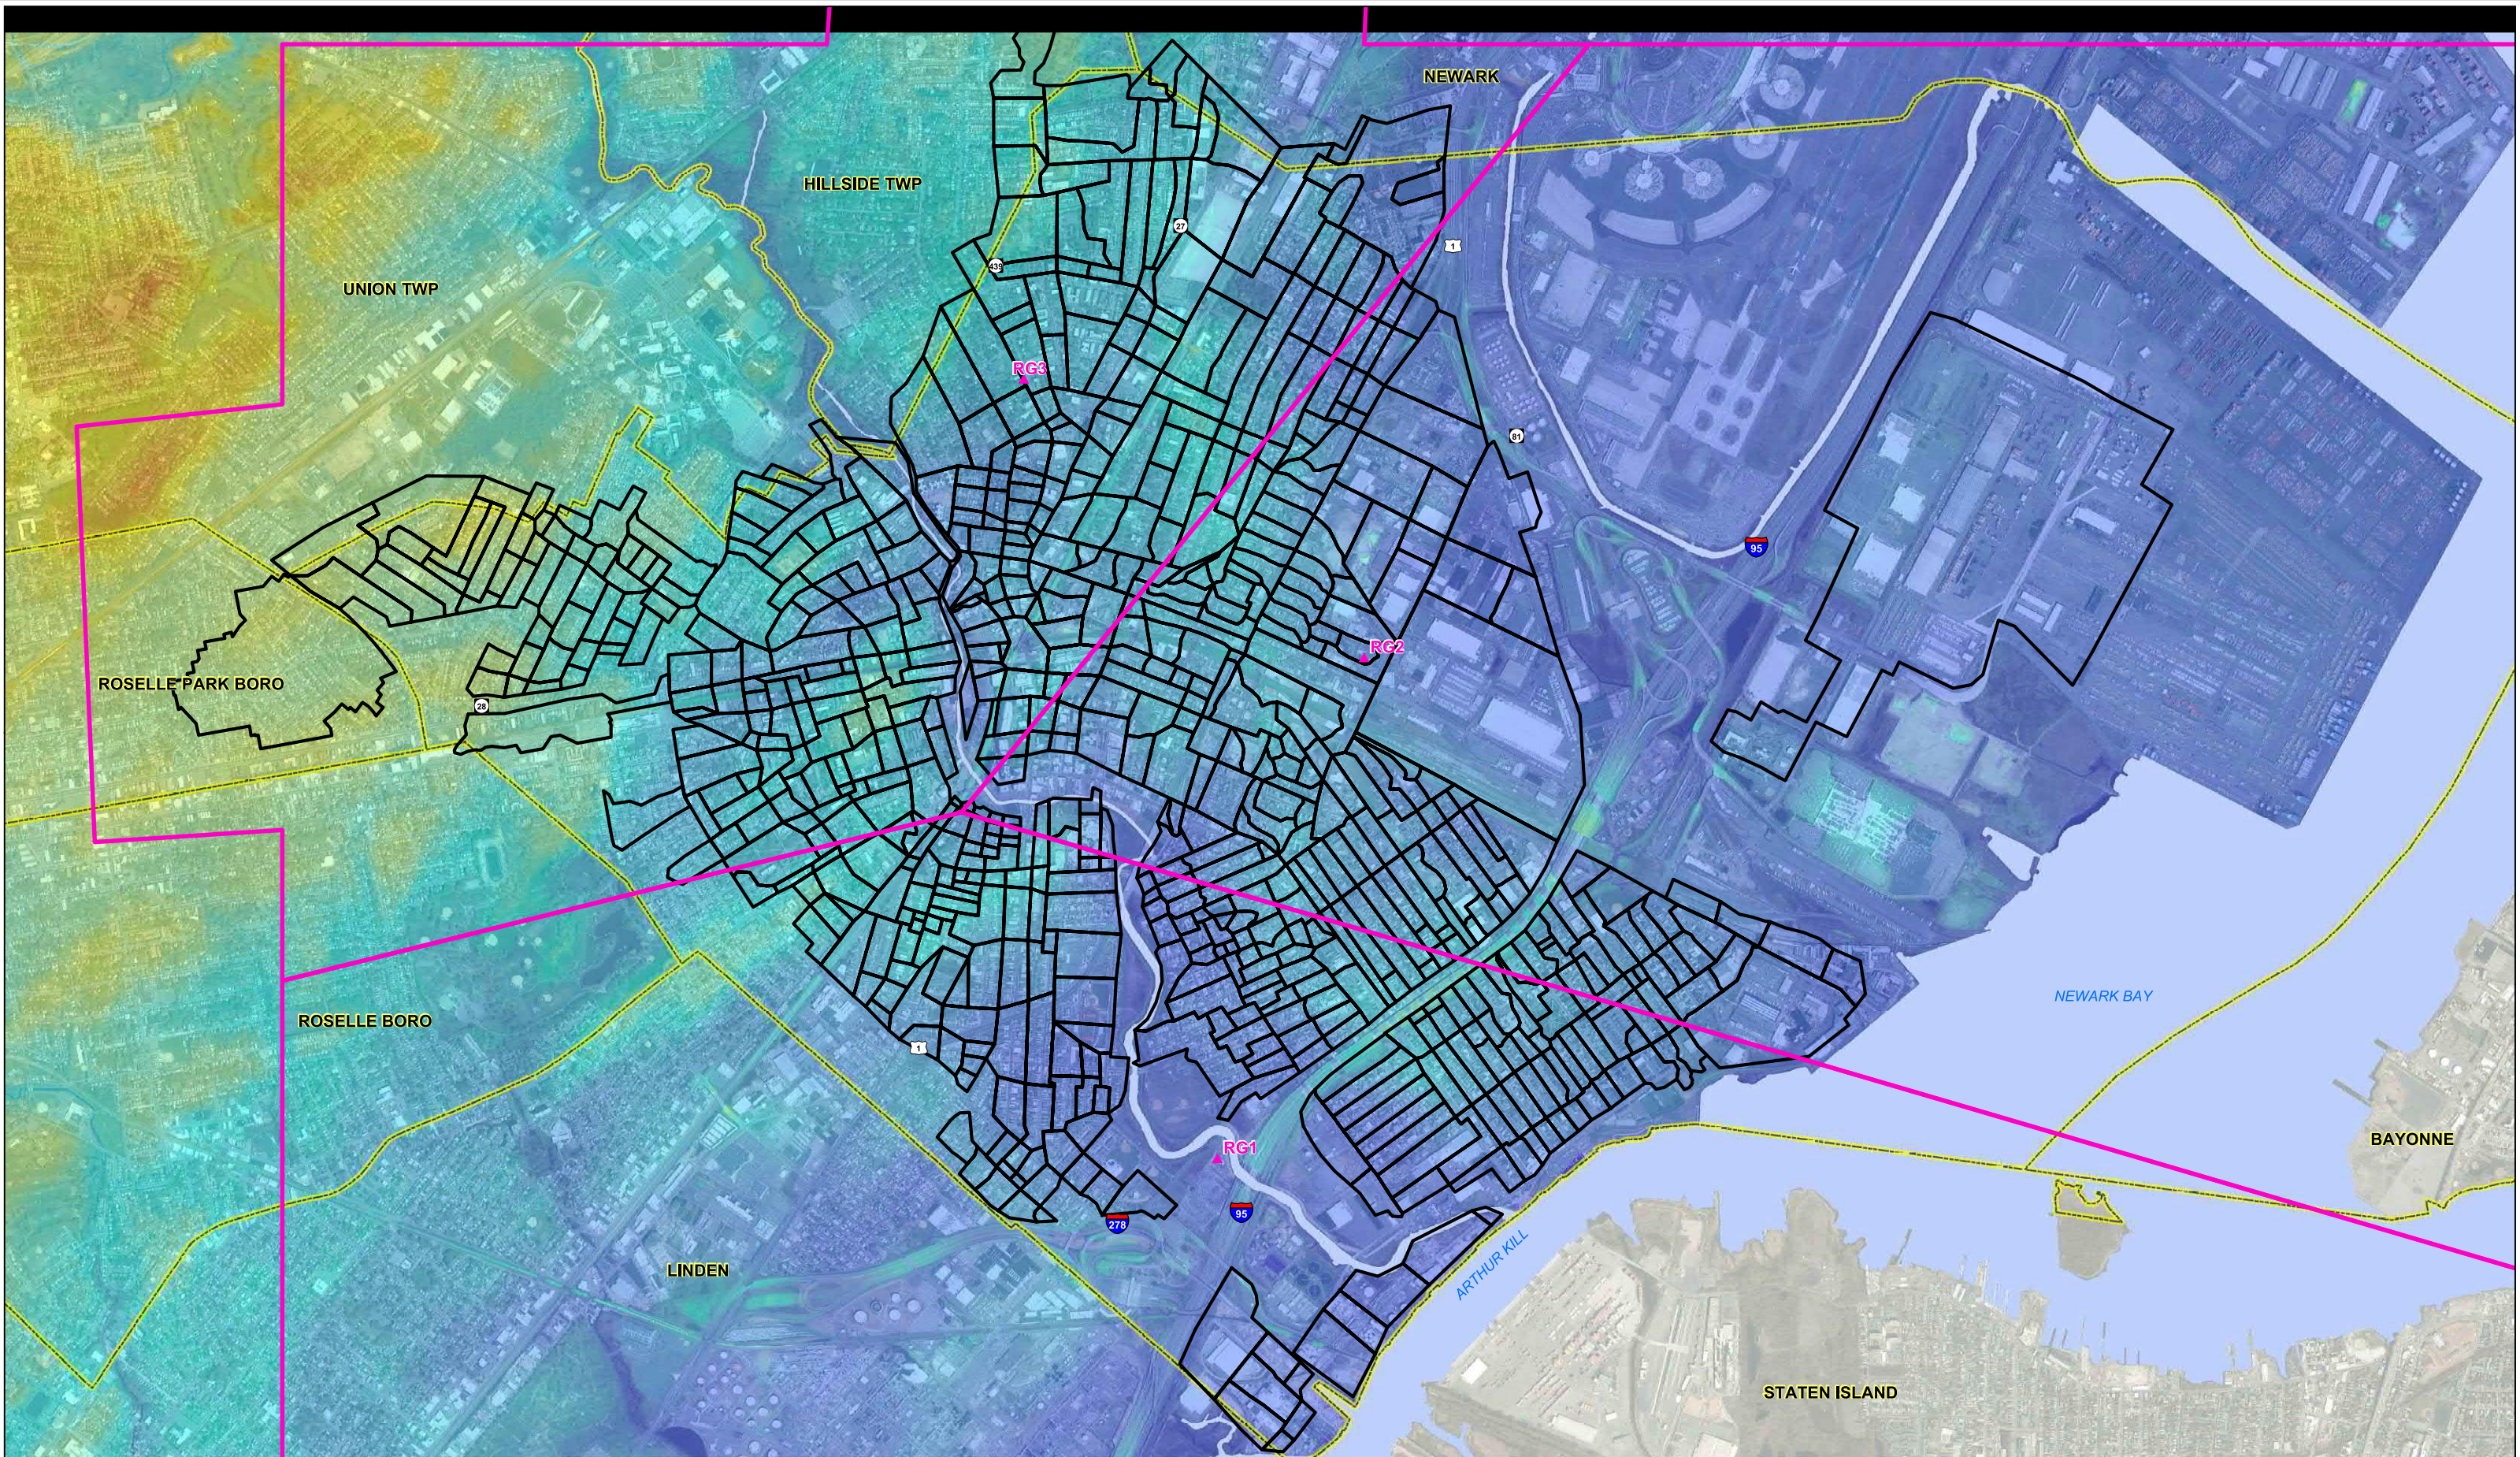

Table 5-2: Start and End Times of Rainfall Events and Calculated Intensities

Storm #	Start Date	End Date	Start Time	End Time	Rain Depth (In)	Rain Duration (Hrs)	Max 1-Hr Rainfall Intensity (In/Hr)
#1	9/9/2015	9/9/2015	15:40	18:30	0.11	2.83	0.22
#2	9/10/2015	9/10/2015	3:05	23:45	0.99	20.67	0.26
#3	9/29/2015	9/30/2015	23:00	8:45	1.39	9.75	0.76
#4	10/2/2015	10/3/2015	4:30	10:00	1.91	29.50	0.31
#5	10/9/2015	10/9/2015	17:25	22:50	0.32	5.42	0.25
#6	10/28/2015	10/29/2015	10:25	9:15	1.65	22.83	0.55
#7	11/10/2015	11/11/2015	8:30	7:15	0.57	22.75	0.12
#8	11/19/2015	11/20/2015	13:35	9:30	1.00	19.92	0.29
#9	12/1/2015	12/2/2015	1:35	23:30	0.60	45.92	0.07
#10	12/17/2015	12/17/2015	11:15	22:30	1.15	11.25	0.35

These rainfall events were then classified into four (4) categories based on their maximum 1-hour intensity and storm duration, namely:

- Low Duration, Low Intensity
- Low Duration, High Intensity
- High Duration, Low Intensity, and
- High Duration, High Intensity
-
- Classification of the storm events into the four categories based on their maximum 1-hour intensity and duration is shown in Figure 5-9.

Figure 5-8: Maximum 1-Hour Rainfall Intensities and Rainfall Depths for Measured Storm Events

Figure 5-9: Storm Classification Based on Intensity and Duration

The distinction between low intensity and high intensity and short duration and long duration was made by assuming the data collected was typical of local rainfall and taking the arithmetic average of the peak hourly intensities and durations. This approach allows the optimal use of

the data collected by ensuring the analysis pulls from the full range of the data collected. This approach does not identify long duration or high intensity in an absolute sense, but the purpose of this exercise is to show that the full breath of data is being used for calibration.

Accordingly, the dividing line between low intensity and high intensity was calculated as 0.32 in/hr. An intensity of 0.32" is also an intensity that is likely to produce runoff from pervious areas. This places three storms in the high intensity category and seven in the low intensity category, this is a reasonable as fewer high intensity storms are expected.

The long duration and short duration the storms were divided into those shorter than 19 hours and those longer. As can be seen there is a wide gap between storms shorter than 12 hours and those longer than 20 hours, making 19 hours a reasonable break point. This resulted in four short duration storms and six long duration storms which is reasonable based on the data collected.

5.4.1 Calibration and Validation Storms Selection

The two rainfall events occurring 11/10/2015 - 11/11/2015 and 12/1/2015 - 12/2/2015 consisted of periods of intermittent low intensity rain and did not exhibit long durations of contiguous rainfall. As such, these storms were deemed inappropriate for calibration and will be excluded from model calibration and validation.

To calibrate the model, a range of storm intensities and durations were selected. To cover a range of conditions, one storm from each quadrant of chart was selected for calibration. In addition, 2 storms were selected for validation, focusing on larger storms from the monitoring period since the control facilities will concentrate around the 5th largest annual storms.

- Calibration Storms
 - 10/9/2015 (Storm #5)
 - 10/28/2015-10/29/2015 (Storm #6)
 - 11/19/2015-11/20/2015 (Storm #8)
 - 12/17/2015 (Storm #10)
- Validation Storms
 - 9/29/2015 (Storm #3)
 - 10/2/2015 (Storm #4)
- Rainfall hyetographs for all measured rainfall events is included in Appendix F of this report.

5.5 Dry Weather Flow Analysis

5.5.1 Identification of Dry Weather Days

Dry Weather Flows (DWF) in a combined sewer system come from two primary sources: a baseflow that represents a constant inflow into the system from the surrounding soil, also called the Ground Water Infiltration (GWI), and a base sanitary flow generated by the population and industries tributary to the sewer, also called the Base Sanitary Flow (BWF). GWI and BWF together comprise the DWF that occurs in a sanitary or combined sewer system. Because the determination of BWF and GWI is not an exact science, various assumptions related to the water consumption return rates and wastewater composition during early morning hours are typically used to help estimate these flow components. Figure 5-10 indicates the various components of DWF. The rainfall derived inflow and infiltration (RDII) component is the sewersheds response to wet weather conditions (precipitation) which is described in detail under Section 5.6.

Separating the baseflow and population flow components of the overall DWF in a sewer is essentially separating the time variable portion (BWF) and the time constant portion (GWI) of the overall sanitary flows. The first step to do the separation is to identify the dry weather days; these are days with minimal rainfall input to the sewer system and as such, the data recorded by flow meters on these days will primarily reflect sanitary flow inputs.

To facilitate the separation of GWI and BWF, the flow meter data was cross examined with the rain gage data to identify the dry weather days. For the purposes of this project, **dry weather days were defined as minimum three (3) days of no precipitation following a day with rainfall more than 0.25 inches, OR, minimum two (2) days of no precipitation following a day with rainfall less than 0.25 inches, AND, no rainfall on that day itself.** It is noted that the criteria for determination of dry weather days was adopted from the QAPP dated Dec 2015, revised June 2016. The goal of this methodology was to identify all flow monitored days that satisfied the dry weather classification used for this project. This criterion was generally used except when examination of the flow data showed exceptions were warranted. As an example, there was a water main break in the City during November 2015 that impacted the flow meters M-15, M-16, M-19, M-23, M-29 and M-30. The impact of the break was evident from the flow meter data which exhibited a sharp increase in pipe flows for an extended period of time without any rainfall. Inclusion of these days as dry weather days can add bias to the DWF estimates. As such, these days were excluded from the analysis. In order to account for noise in the gage data, a daily rainfall total of 0.02 inches or less were treated as no rainfall for the dry weather days determination.

Figure 5-10: Flow Components of Combined Sewer System

Overall, a total of seventy-two (72) dry weather days were identified during the Aug 22 – Dec 21, 2015 flow monitoring period (121 days total). Of the 72 dry weather days, fifty-two (52) were weekdays while twenty (20) were weekend days. Table 5-3 identifies the days in the overall monitoring period that were identified as dry weather days at the conclusion of this step:

Table 5-3: Summary of Dry Weather Days for the Monitoring Period

Date	Dry Days	Weekend/ Weekday	Precipitation RG1 (in)	Precipitation RG2 (in)	Precipitation RG3 (in)

5.5.2 Meter Data Analysis

Once the dry weather days were identified, the days were split into weekdays and weekends categories. This breakdown was based upon the fact that ICM has the ability to use only two (2) diurnal patterns to model sanitary flows. The assumption is that weekdays and weekend days are essentially the same. For the most part, the data passed the statistical tests and validated

the two (2) category breakdown. Once the two (2) categories of data were verified, the metered flows for the dry weather days were combined by averaging similar time steps together throughout a full 24-hour day. Statistical tests were again performed to identify days that could be classified as outliers and not included in the average. The statistical cutoff was any values having an absolute value greater than two (2) standard deviations from the mean. Another reason for excluding certain potential dry weather days was if the data showed significant irregularities. One such example was the water main break during November 2015 indicated earlier. These days were identified by visually inspecting the data and looking for days with missing data or data grossly different from the typical trends. Once this data cleaning process was completed, average DWF were established for the typical weekday and weekend for each flow meter.

The next step was to extract the GWI component of the overall DWF. Infiltration enters the sewer system through openings such as displaced or open pipe joints, cracks, fractures and breaks in the fabric of the main sewer and lateral connections, and manhole chambers. This usually occurs when the groundwater level is above the sewer invert level and may be seasonally influenced. The infiltration component was extracted by assuming the groundwater infiltration was 88% of the observed minimum night time flows. This is a widely used technique to extract GWI from DWF. The difference between the overall DWF and the GWI corresponds to the BWF (population input). After the BWF sanitary flows were separated, diurnal patterns for these flows were calculated, each for weekday and weekend. The diurnal patterns are represented by hourly peak flow factors that were calculated by the ratio of the flow value for an individual time step to the average value of the entire day. Once all the hourly factors were calculated for all flow meters, these were input into ICM model, along with the calculated BWF and GWI, for dry weather flow generation. A sample of DWF and peak flow factors curves for weekend and weekday are included in Figure 5-11 below, based on data from flow meter M-5. Calculated DWFs and weekend/weekday peak flow factors for all meters are included in Appendix E of this report.

5.5.3 Seasonality Analysis of Groundwater Infiltration (Baseflow)

Literature suggests that groundwater infiltration into a sewer system is expected to vary seasonally. Seasonal variation in infiltration is common due to corresponding seasonal variation in groundwater levels. As indicated earlier, the two groundwater gauges did not register any groundwater readings during the flow monitoring period. As such, no measured data was available to verify a potential seasonal variation in groundwater infiltration.

To further investigate a possible seasonal variation, the flow meter data for identified dry weather days was divided into three parts: data from Aug 22 through Sept 15 (Summer), from Sept 16 through Nov 30 (Fall), and then from Dec 1 through Dec 21 (Winter). The idea was to categorize the data into the three seasons the monitoring period spanned and identify any obvious patterns or trends in the data. The diurnal flow plots for these three periods were visually compared for each flow meter to confirm a seasonal variation. Although some meters exhibited slight variation between these three periods, overall, no pattern was observed that indicated a seasonal variation in groundwater infiltration. This is expected, as the flow monitoring program extended for a 4-month duration only, it is often easier to identify seasonal variation when flow monitoring is conducted for a longer duration (across four seasons, multiple years). Performing flow monitoring for durations longer than the monitoring period was beyond the scope of this study. It is also noted that the groundwater infiltration is a small component of the overall combined sewer flows. As such, slight variation in computing such is not expected have a significant impact on the overall model calibration. Two example plots are included in Figure 5-12 for flow meter M-8. The yellow lines represent 5-minute flow data between Aug 22

through Sept 15 (Summer), grey lines represent Sept 16 through Nov 30 (Fall), and the green lines represent Dec 1 through Dec 21 (Winter). As can be seen, for both weekdays and weekends, no definite pattern that distinguishes flow meter data from one period to the other can be identified.

5.5.4 Metershed Delineation

As indicated in the earlier sections of this report, out of the forty (40) flow meters installed, fourteen (14) flow meters have no upstream hydraulic influence or hydrologic input, i.e. these meters are located near the headwaters of the overall sewershed, unaffected by flow regulators or other flow control devices. These meters were M-2, M-5, M-8, M-9, M-11, M-12, M-16, M-19, M-22, M-25, M-27, M-28, M-34 and M-40 respectively. For the purposes of this report, these meters will be referred to as unique meters.

Influent sewersheds to these unique meters were delineated using available GIS and publicly available DEM data indicated earlier. The idea is to correlate the sewersheds physical characteristics to the corresponding flow meter data from which population based flow estimates (sanitary flows, gallons/capita/day) can be estimated. This is an essential step towards overall model calibration; it is impractical and time consuming to meter the entire City's combined sewer system. Instead, meters were installed at representative locations to capture the entire

Figure 5-11: DWF Peak Factors

Figure 5-12: Sample Plots for Test of Seasonal Variation in GWI

spectrum of flow variations across the system. The flow characteristics of each metershed is extrapolated to individual sewersheds that fall within that metershed. The process is repeated until all individual sewersheds are assigned the flow characteristics from their respective metersheds. For the unmetered areas of the City, the flow characteristics are extrapolated from metered areas with similar physical characteristics (e.g. flow characteristics of a meter located in a primarily residential area can be extrapolated to another area of the City that is residential).

5.5.5 Population Analysis and Per-Capita Sanitary Flows

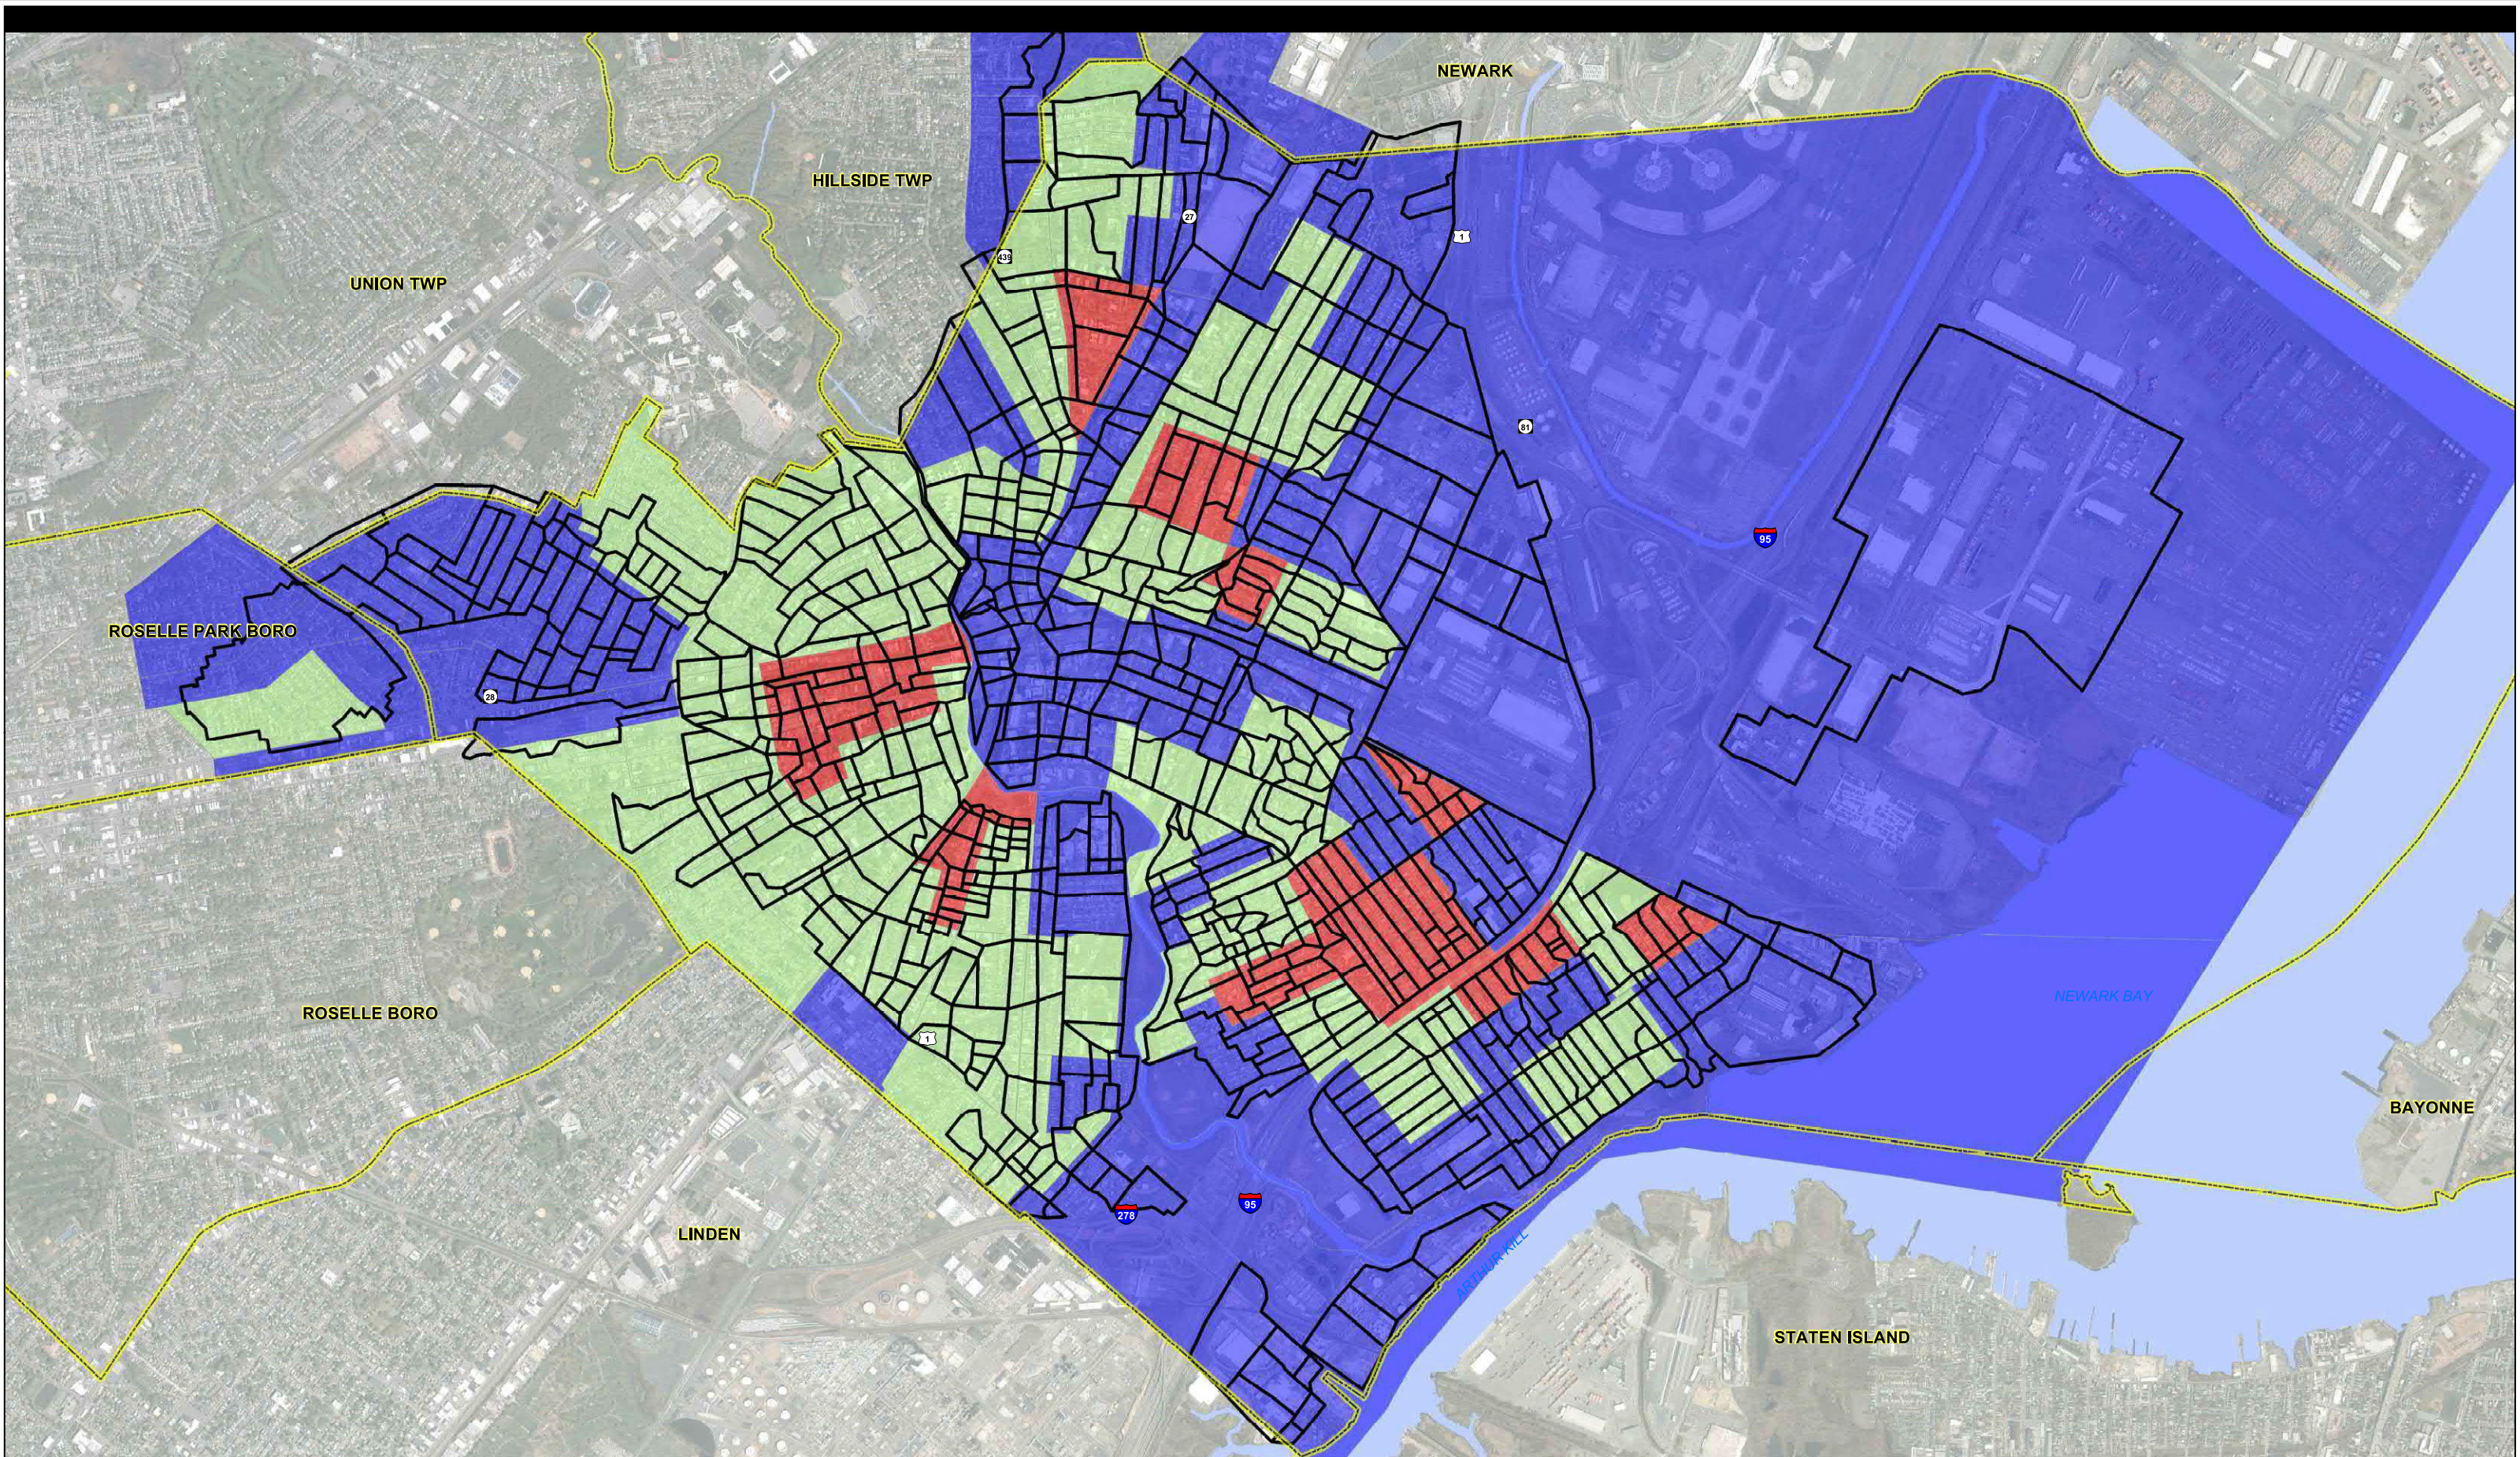

The 2015 American Community Survey (ACS) total population estimate for Union County, NJ was used in this study. This data is maintained and published by the US Census Bureau. Census block level population data is publicly available from the US Census Bureau's American Fact Finder web platform. The population count is available for download in table format, while the census blocks are available in GIS format. The blocks were normalized by their acreage to derive population density for each census block. This GIS dataset was then compared with the delineated metersheds to calculate total population at each metershed level (Population Density in Population/Acre x Metershed Acre = Population of Metershed).

Once the population count by metersheds were available, this data was correlated with the flow meter data. Recall that as part of the flow meter data analysis, the sanitary component of the overall DWF was extracted (in Million Gallons/day) from the recorded meter data. This value divided by the metershed population provides an estimate of the sanitary flow rates at each metershed level in gallons per capita per day (GPCD). Fourteen (14) unique wastewater profiles were created in ICM for these unique metersheds. Each such wastewater profile had the GPCD flow estimate as the average sanitary flow, coupled with the diurnal peak factors for weekday and weekends calculated earlier.

The population analysis was re-run with the 694 individual sewersheds. Each sewershed was assigned a wastewater profile corresponding to the metershed they fall under. With this setting, each sewershed will generate sanitary flows utilizing the sewershed population and the GPCD estimates from meter data. The population density across the studied sewersheds based on 2015 ACS data is shown in Figure 5-13. The detailed process workflow for estimating the sanitary component of the overall DWF is shown under Figure 5-15.

5.5.6 Industrial Areas Sanitary Flows Generation

Three unique areas were observed in the City limits where the GPCD estimates based on the population and flow meter data analysis did not reflect real world conditions. The first area (area 1) is located towards the east adjacent to the Newark Airport and Elizabeth Port, along Dowd Avenue and Trumbull Street. The second area (area 2) is located adjacent to and immediately north of the New Jersey Turnpike, commonly known as the Bayway area. The third area (area 3) is located south of the Newark Airport that ultimately discharges sanitary flows only to the Kapkowski Road Pump Station. The pump station discharge connects to the Easterly Interceptor by means of a 16" ductile iron force main. These areas are primarily industrial that include stores, warehouses, shopping centers, and industrial facilities. The GPCD estimates for areas 1 and 2 were derived based on the gross impervious area (in square foot) of these sewersheds, and using 0.075 gallons/day/square foot (gpd/sf) of unit sanitary flow. This is in accordance with N.J.A.C. 7:14A, Subchapter 23: Technical Requirements for Treatment Work Approval Applications that recommends using a 0.1 gpd/sf of gross area to estimate sanitary flows from stores and shopping centers. This was set up as a separate wastewater profile in Infoworks ICM, and the corresponding sewersheds were tagged to utilize this for sanitary flow calculations. For area 3, a GPCD estimate of 0.04 MGD based on the Kapkowski Road Pump Station records was adopted for modeling purposes.

5.5.7 Inch-Mile Analysis for Groundwater Infiltration (GWI)

Groundwater infiltration into the sewer system can be estimated by performing an Inch Diameter Mile Length (IDM) analysis. Basically, the product of the pipe diameter (inches) to its length (mile) is calculated and used as a representative factor to estimate groundwater infiltration, as shown in Figure 5-14. For the purposes of this study, the GIS dataset of the existing sewer system was used. This calculation was performed at a metershed level so that the calculated inch-mile values could be correlated with the flow meter data.

Once the IDM estimate by metersheds were available, this data was correlated with the flow meter data. Recall that as part of the flow meter data analysis, the groundwater infiltration component of the overall DWF was extracted from the recorded meter data (in Million Gallons/day). An infiltration factor was developed for each metershed in the form of:

$$I - Factor = \frac{GWI \text{ from Meter Data (MGD)}}{IDM \text{ for the Metershed (In - Mi)}}$$

IDM values for each of the 694 individual sewersheds were also computed. The final groundwater infiltration at each individual sewershed level was then calculated as:

$$Sewershed \text{ GWI} = I - Factor \times Sewershed \text{ GWI (In - Mi)}$$

The computed groundwater infiltration for each sewershed was then used as calibration parameter that was adjusted at sewershed level to match the model hydrographs with flow meter data. The detailed process workflow for estimating groundwater infiltration component of the overall DWF is shown under Figure 5-15.

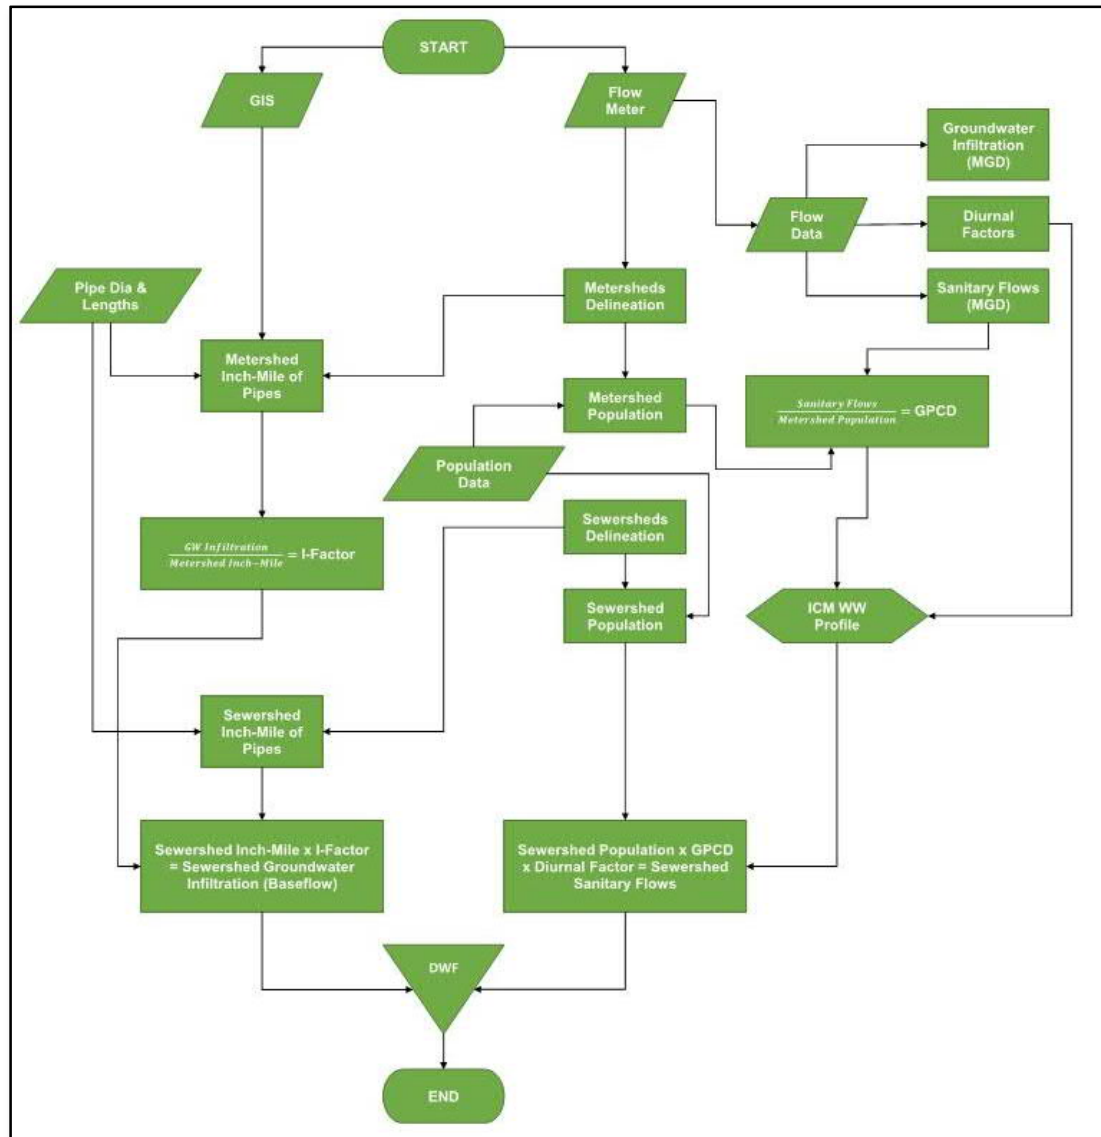

Figure 5-14: Inch Diameter Mile Length IDM Analysis

5.5.8 ICM Wastewater Profile Development

Infoworks ICM generates dry weather flows based on “Wastewater Profiles” associated with each sewershed. Profiles are placeholders where the GPCD flow information along with weekday and weekend peak flow factors are stored. These are combined with the population (per capita) input at sewershed level to generate sanitary flows. Sanitary flows are added to the groundwater infiltration assigned at a sewershed level to calculate overall dry weather flows. Calculation steps to derive these individual components are described above. Figure 5-15 graphically summarizes the overall process of generating Dry Weather Flows for sewersheds.

Figure 5-15: Process Flow for Determination of DWF Inputs from Meter and GIS Data

The calculated sanitary flows and groundwater infiltration for the unique flow meters are summarized in Table 5-4.

5.6 Wet Weather Flow Analysis

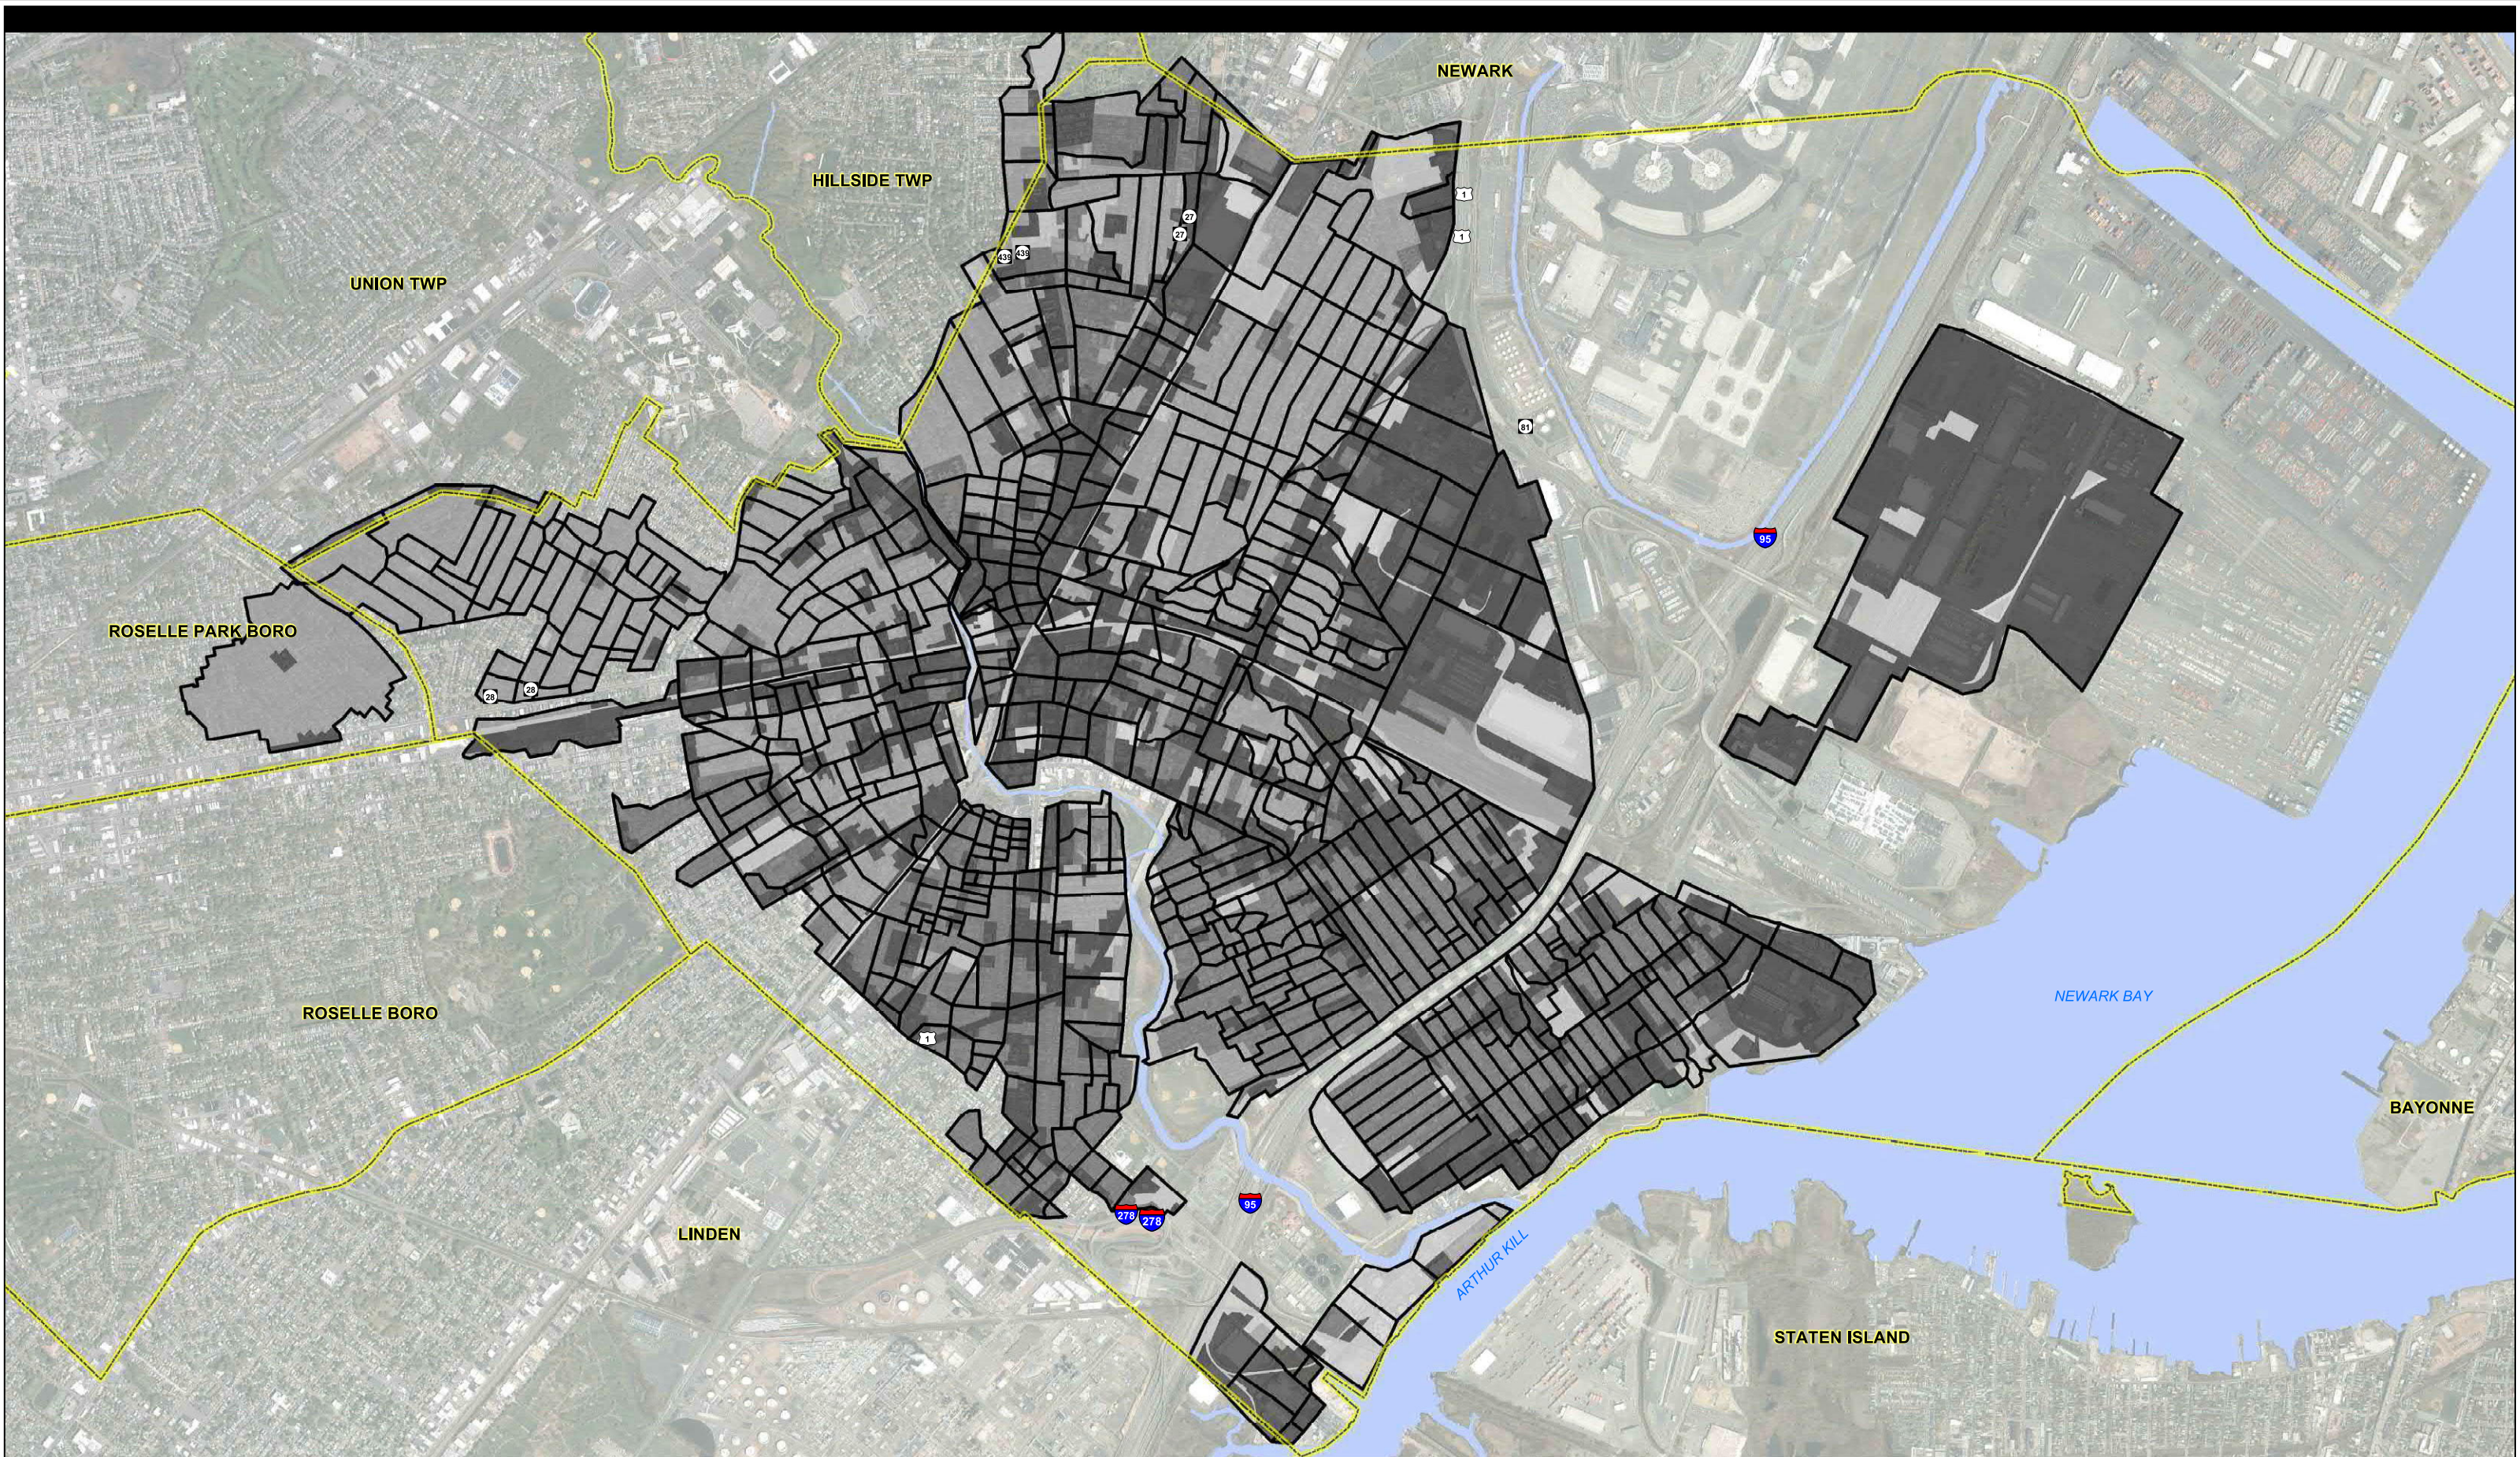

5.6.1 Impervious Areas Calculations

Statewide land use – land cover data is publicly available through the New Jersey Department of Environmental Protection (NJDEP), Bureau of GIS. The latest available data that was used for this study is dated 2012 that was updated by NJDEP in 2015. This data divides all areas by unique land cover type polygons and captures the percent imperviousness of each polygon depending on the land cover type.

The percent impervious attribute of each land cover polygon in the NJDEP dataset was used to calculate the acreage of impervious and pervious land surfaces for each metershed and individual sewershed areas. The percent imperviousness of each land cover polygon is listed under the IS12 attribute field of the NJDEP land cover dataset. This dataset was compared with metersheds and individual sewersheds to calculate the impervious and pervious (total minus impervious) acreages of all sewersheds used in this analysis. Once the percent impervious was calculated, the meter data was correlated with the impervious acreages to compute the initial abstraction and runoff coefficients for the unique metersheds. The variation in percent imperviousness is illustrated in Figure 5-16.

5.6.2 Estimation of Initial Abstraction and Runoff Coefficients

Initial abstraction and runoff coefficients are the fundamental concepts of conversion of rainfall to runoff. Initial abstraction, also sometimes referred to as depression storage, is the volume that must be filled prior to the occurrence of surface runoff on both pervious and impervious surfaces. It represents the “loss” caused by phenomena such as surface ponding, surface wetting, interception and/or evaporation that depletes an initial fraction of the rainfall after which surface runoff occurs, regardless of the storm intensity or duration. Once runoff begins, the volume of runoff generated for a given volume of rainfall is dependent on the surface type. Runoff coefficient is the ratio of the total volume of runoff to total rainfall volume, over the study area.

To estimate the initial abstraction and runoff coefficient for each metershed, the flow meter data was analyzed for the wet weather days; these are the ten (10) measurable storm events indicated under Section 5.4. The idea was to analyze the flow meter data on the days of known rainfall, subtract the previously computed dry weather flow and estimate the portion of flow which is rainfall induced inflow. Figure 5-17 provides a graphical representation of typical flow meter response to rainfall, the baseline dry weather flow, and rainfall induced inflow. The area between the wet weather flow (black line) and the dry weather flow (orange line) line represents the volume of rainfall induced inflow, and is of primary interest. It is noted that the impervious areas within the sheds were assumed to be directly connected impervious areas (DCIA). This means that roadway impervious connects to a storm sewer system; rooftop impervious connects to a storm sewer system through roof leaders and downspouts. This assumption is supported by actual conditions as the impervious areas under most instances connect to the combined sewer system. There may be instances where the roof leaders outflow into the yard where the runoff travels for a short distance before entering the sewer system, but overall, the impact of such is de minimis to the flow generation characteristics of this system.

Figure 5-17: Typical Flow Meter Response Showing DWF and Rainfall induced Inflow

Once the rainfall induced inflow was computed, its value was compared to the volume of rainfall. Due to the initial abstraction of land surface, there will be a lag before runoff will begin. When the volume rainfall is plotted against volume rainfall induced inflow, the x-axis intercept represents the lag due to initial abstraction. Once runoff has begun, the slope of the plotted line represents the runoff coefficient. These two are the primary inputs in ICM for wet weather flow generation. Figure 5-18 provides an example plot and analysis for calculation of initial abstraction and runoff coefficients from flow meter data.

Figure 5-18: Extraction of Initial Abstraction and Runoff Coefficient from Flow Meter Data

Table 5-5 provides a summary of the initial abstraction and runoff coefficients calculated for all the unique metersheds. These values were then used as a guide to create different runoff surfaces in ICM that were used for model calibration.

Table 5-5: Calculated Initial Abstraction and Runoff Coefficients from Flow Meter Data

Meter #	Initial Abstraction (Inches)	Runoff Coefficient
2	0.13	0.39
5	0.06	0.43
9	0.04	0.23
11	0.31	0.65
12	0.01	0.37
16	0.22	0.32
19	0.23	0.40
22	0.17	0.97
25	0.31	0.21
27	0.13	0.73
40	0.11	0.18

Once the runoff surfaces were created, they were assigned to individual sewersheds based on the metershed they fall under. Similar to dry weather flow steps explained earlier, for unmetered areas of the City, computed data from these metersheds were assigned based on similar physical characteristics. The initial abstraction and runoff coefficients for the runoff surfaces were then used as calibration parameters that were adjusted to match the model hydrographs

with flow meter data. Using the initial abstraction, the runoff coefficient and the impervious and pervious area acreages calculated earlier, peak flows were generated in Infoworks ICM for all sewersheds.

5.6.3 Other Parameters for Wet Weather Flow Generation

Some other parameters of interest in this regard are the underlying soil's infiltration capacity, the slope, sewershed width, and the surface roughness of the overland flow path.

Infiltration is a significant component of the hydrologic flow generation process. Soils have varying capacities to infiltrate water. The soil's infiltration capacity influences the runoff generation after surface runoff has begun. The higher the infiltration capacity, less will be the runoff generated. When the rainfall intensity is less than the infiltration capacity, all of the rainfall reaching the ground can infiltrate. But if the rainfall intensity exceeds the infiltration capacity, infiltration will occur only at the infiltration capacity rate, and water in excess of that capacity will be stored in depressions, become surface runoff, or evaporate. It is noted that the soil infiltration capacity does not remain constant throughout the duration of the rainfall; in fact, the capacity is maximum when rainfall begins, and decreases exponentially as the ground starts to saturate. Once the storm is over, the infiltration capacity slowly reverts back to its original state. In general, the initial infiltration capacity of a dry soil is high. As rainfall continues, and the soil becomes saturated, it diminishes to a relatively constant rate (ultimate capacity).

There are variety of ways to model soil infiltration for pervious areas in ICM. Perhaps the most common and best known is the Horton method. Horton's method is empirical in nature and follows the following exponential equation to predict the reduction in infiltration capacity over time:

$$f_p = f_{\infty} + (f_0 - f_{\infty})e^{-k_d t}$$

Where,

f_p - Initial infiltration capacity of soil (ft/sec)

f_{∞} - Minimum or equilibrium value of f_p at $t = \infty$ (ft/sec)

f_0 - Maximum or initial value of f_p at $t = 0$ (ft/sec)

t - Time from beginning of storm (sec)

k_d - Decay coefficient (sec^{-1})

The equation indicates that if the rainfall supply exceeds the infiltration capacity, infiltration tends to decrease in an exponential manner.

A typical Horton infiltration curve is shown under Figure 5-19.

Sewershed slope reflects the average slope along the pathway of overland flow to the sewershed outlet. The sewershed width is the width of overland flow in a sewershed before the runoff enters the pipe system.

The width parameter tells the program how long the runoff must travel to the outfall, an estimate of the runoff travel time. For the purposes of this study, sewershed slopes were computed from DEM data for each individual sewershed. The width parameter was estimated as the square root of the area (assuming an idealized square shaped sewershed) as a starting point, and was used as a calibration parameter that was adjusted to match the model hydrographs with flow meter data. Since the entire study area were distributed into small size sewersheds, most of

Figure 5-19: Horton Infiltration Curve

which is piped, the overall travel time of runoff is short. As such, the watershed width parameter did not have a pronounced impact on the runoff generation characteristics.

The surface roughness for a runoff surface represents the obstruction to overland runoff flow from variability in surface features. This was accounted for by selecting typical Manning's roughness coefficient values for pervious and impervious surfaces in ICM.

5.7 Model Calibration

5.7.1 Calibration Objectives

The value and usefulness of any computer model representation of a sewer system is dependent upon how well the model can simulate the real-world performance of the combined sewer system. To formulate a model that closely matches measured values, a process of calibration and validation is performed to refine the model input parameters to best match the flow meter data collected in the field. Calibrating a sewer collection system model consists of changing various characteristics of the sewer conveyance network and sewersheds in the hydraulic model to achieve close correlation between predicted and observed flows, depths and velocities based on the monitoring data collected during the 4-month monitoring program. It is also critical that the model accurately reproduce the flow monitoring data collected at hydraulically important locations such as CSOs, interceptors, and the pump station facilities.

The calibration process typically takes multiple time periods from the flow monitoring data and refines the model input parameters to achieve a good fit with the measured data across a wide variety of system conditions (i.e., wet weather calibration will typically involve selecting storms

of different intensity and durations). The validation process follows the calibration process by providing a sample of the monitoring data for the model that is completely independent of those used for the calibration process. If the model can reasonably reproduce the results of the validation event(s), the model is considered validated.

Calibration is typically performed in two stages. The first stage is completion of dry weather flow (DWF) calibration to ensure the hydraulics of the model are similar to the actual sewer system under typical dry weather (sunny day) conditions. Typically, only minor model adjustments are needed for the H&H model to accurately reproduce the DWFs since the DWF inputs are directly calculated from the flow meter data and known population statistics. After successfully completing DWF calibration, the model is evaluated under wet weather conditions as the second stage. Wet weather calibration ensures the H&H model accurately mimics the sewer system's response to rainfall. Since the hydrologic factors that affect wet weather flow generation are more complex, more user adjustment of variables to achieve an acceptable agreement between the model predicted output and the observed flow meter data is often needed. The overall goal of the model calibration process is to adjust the internal parameters so that the model predictions of flow, velocity, and depth match the observed flow monitoring data collected from the observed rain events.

5.7.2 DWF Calibration

Dry weather calibration was based upon matching the dry weather weeks as described in Section 5.5. Statistical criteria based on the WAPUG Standards: Wastewater Planning Users Group, Code of Practice for the Hydraulic Modeling of Sewer Systems, version 3.001, dated November 2002, were applied to give a numerical evaluation of each flow meter used for model calibration and verification. In addition, some "common sense" checks like no overflows during dry weather days were also employed during this process.

Table 5-6 summarizes the WAPUG criteria for DWF calibration. The WAPUG criteria suggest changing calibration parameters to achieve simulated peak flows and volumes within $\pm 10\%$ of the measured values. It is noted that slight variation between simulated and measured is expected. For flows of smaller magnitude, it becomes important to evaluate the results based on the actual flow value instead of the percentage difference since the percent values tend to be large for meters with very small flows.

Table 5-6: WAPUG DWF Calibration and Validation Criteria

Criteria	Calibration Range	Notes
Peak Flow Rate	$\pm 10\%$ or 0.1MGD	Use of actual value instead of percentage applied to meters with very small flows
Volume	$\pm 10\%$ or 0.1MGD	Use of actual value instead of percentage applied to meters with very small flows
Timing of Peaks	± 1 Hour	For both peaks (high flows) and troughs (low flows)
Shape	The shape of the measured and simulated curves should be similar for flow and depth	

Source: Wastewater Planning Users Group, Code of Practice for the Hydraulic Modeling of Sewer Systems, Nov 2002.

Figure 5-20 is an example plot of measured vs. simulated flows obtained from the DWF calibration process undertaken for this study. DWF calibration plots for all flow meters are provided in Appendix D.

The black line represents the measured (metered) flow hydrograph, and the red line represents the simulated (modeled) hydrograph, over a 2-week dry weather flow period with no rainfall. The goal of model calibration was to make the simulated hydrograph match the measured

Figure 5-20: DWF Calibration Example Plot

hydrograph as closely as practicable, by varying model input parameters that impact flow generation. As can be seen from the Figure 5-20, the model was able to closely predict the peaks and troughs of DWF, and also accurately capture their timings and the general shape of the DWF hydrograph. Overall, the dry weather flow results from the model compared favorably with those from the flow meter data. Dry weather flow calibration graphs for all flow meters are provided in Appendix D of this report.

5.7.3 Flow Depths Calibration

A comparison of unsurcharged flow depths was conducted between the modeled and meter data. The WAPUG criteria requires unsurcharged flow depths to be within ± 4 inches (± 100 millimeters). The Manning's roughness coefficients discussed under Section 5.2.3 were varied within acceptable ranges to make the modeled flow depths for DWF match the metered flow depths.

Figure 5-21 summarizes the results of the flow depth calibration. As can be seen that out of the fourteen (14) unique meter locations, the model was able to match the unsurcharged flow depths for at least nine (9) locations. For meter M-12, the difference (delta) of simulated to measured unsurcharged depth was within 4 to 6 inches. For meters M-2, M-8, M-11 and M-28, the difference was within 6 to 8 inches. There is a point of diminishing return in this instant, for example, where changing Manning's roughness values any further for RCP material may help meter M-8 and M-11 results, while it hurts the results for meter M-2 and M-12. Overall, these results compare favorably, and although the model was not able to exactly match the

Figure 5-21: Unsurcharged Flow Depth Calibration Results for DWF

unsurcharged flow depths at some meter locations, the model results generally conformed to the measured flow meter data. This is typical of the model calibration process where engineering judgment is required to determine the limits of changes in input parameters to match target values.

5.8 Wet Weather Flow Calibration

The process of calibrating the hydraulic model for wet weather flow is more complex than for dry weather flows. The idea is to apply pre-selected rainfall events (calibration and validation storms) to the model, compare the wet weather flow response to the corresponding measured data for those periods, and adjust model parameters to match the flow meter response. Table 5-7 summarizes the WAPUG criteria for WWF calibration.

Table 5-7: WAPUG WWF Calibration and Validation Criteria

Criteria	Calibration Range	Notes
Peak Flow Rate	+25% to -15%	Use of actual value instead of percentage applied to meters with very small flows
Volume	+20% to -10%	Use of actual value instead of percentage applied to meters with very small flows

Criteria	Calibration Range	Notes
Timing of Peaks	Timing for peaks (high flows) and troughs (low flows) should be similar having regard to the duration of the event	
Shape	The shape of the measured and simulated curves should be similar until the flow has substantially returned to DWF rates	

Source: Wastewater Planning Users Group, Code of Practice for the Hydraulic Modeling of Sewer Systems, Nov 2002.

- **Storm #5 (10/9/2015)** – This storm had the least amount of total rainfall (0.32 inches) and rainfall duration (5.42 hours), and the least 1-hour maximum rainfall intensity (0.25 inches/hour). Based on this, the event was categorized as a low duration-low intensity calibration event.
- **Storm #6 (10/28/2015-10/29/2015)** – This storm had a total rainfall of 1.65 inches over a duration of 22.83 hours, and a 1-hour rainfall intensity of 0.55 inches/hour. Based on this, the event was categorized as a high duration-high intensity calibration event.
- **Storm #8 (11/19/2015-11/20/2015)** – This storm had a total rainfall of 1 inch over a duration of 19.92 hours, and a maximum 1-hour rainfall intensity of 0.29 inches/hour. Based on this, the event was categorized as high duration-low intensity calibration event.
- **Storm #10 (12/17/2015)** – This storm has a total rainfall of 1.15 inches over a duration of 11.25 hours, and a maximum 1-hour rainfall intensity of 0.35 inches/hour. Based on this, the event was categorized as low duration-high intensity calibration event.
- **Storm #3 (9/29/2015-9/30/2015)** – This storm had a total rainfall of 1.39 inches over a duration of 9.75 hours, and a maximum 1-hour rainfall intensity of 0.76 inches/hour which was the largest amongst all the measured rainfall events. As such, this storm qualified as a good candidate for model validation as this has the rainfall depth and duration similar to other calibration storms but provides an upper bound check based on maximum 1-hour rainfall intensity.
- **Storm #4 (10/2/2015-10/3/2015)** – This storm has a total rainfall of 1.91 inches over a duration of 29.50 hours, both being the maximum amongst all the measured rainfall events, and a maximum 1-hour rainfall intensity of 0.31 inches/hour, which roughly falls between the calibration storms. As such, this storm qualified as a good candidate for model validation as this provides an upper bound check for events with large rainfall depths and durations but moderate rainfall intensity.

Overall, the hydraulic model's performance compared acceptably with the measured flow meter data. Differences between the simulated and measured flow data typically related to sudden peak inflows, but overall flow volumes and peak flows matched well. The goodness-of-fit in terms of the flow volumes is the most important when it comes to wet weather flow calibration and validation. Goodness-of-fit plots for all ten (10) measured rainfall events are included under Figure 5-22. The goodness-of-fit plots for all flow meters across the calibration and validation events show that the model generally provided good simulation of flow generation and overall system hydraulics and performed well under varied rainfall totals, durations and intensities. Calibration charts and individual flow meter calibrations are included in Appendices G and H.

A challenging aspect of the wet weather calibration was the effects of operating decisions at the Trenton Avenue Pump Station necessary to maintain the pumping discharge to the JMEUC treatment facilities below the contractual limits. The Trenton Avenue PS operations influence the flow depths and rates within the Easterly and Westerly Interceptors, particularly for the pipe reaches upstream of the station for a considerable distance. To limit wet weather pumping rates and minimize impacts on the pumping equipment, station operators make manual adjustments to influent gate positions and pump controls based on experience and judgements for the ever-

varying event conditions. These operator control decisions are extremely difficult to incorporate into the mathematical models as they do not fit into specific rules that reference readily available input data. The effects of the operator adjustments can be seen in certain wet weather calibration results for meters on the interceptors in the vicinity of the pump station.

As can be seen in Figure 5-22, the overall model results match the metered data closely for the ten (10) rainfall events that were captured during the monitoring period. Some outliers can be observed in the plots above which may be expected, but the majority of the simulated flow values fall on the 45-degree line which indicates a good correlation between the simulated and measured flows. Flow hydrographs for all meters across all calibration and validation storms are included in Appendix G.

6 Receiving Water Quality Monitoring and Modeling

6.1 Background

The NJPDES CSO Permits direct permittees to implement a Compliance Monitoring Program (CMP) adequate to verify existing ambient water quality conditions for pathogens and evaluate the effectiveness of future CSO controls related to compliance with water quality standards (WQS) and the protection of designated uses. Data gathering conducted in the initial CMP phase is to inform the selection of appropriate CSO controls and follow-up water quality monitoring is to be performed at intervals as determined by the NJDEP based on the implementation schedule in the approved LTCP, but no less than once per permit cycle. Permittees are to use NJDEP approved hydrologic, hydraulic, and water quality models to simulate the existing conditions and conditions as they are expected to exist after construction and operation of the chosen alternative(s). The permits require permittees to evaluate the practical and technical feasibility of the proposed CSO control alternative(s), and water quality benefits of constructing and implementing various remedial controls and combination of such controls. Per the NJPDES CSO Permits, pathogens are the pollutant parameters of concern for ambient water quality monitoring and WQS compliance.

Accordingly, the City of Elizabeth is a participating member of the NJ CSO Group, which is a collaboration of various CSO permit holders to share resources and services on a regional basis. Members of the NJ CSO Group have agreed to cooperatively conduct a regional Compliance Monitoring Program to satisfy various permit conditions, with the Passaic Valley Sewerage Commission (PVSC) serving as the program manager. The program includes ambient in-stream monitoring and other work necessary to define the baseline conditions of the CSO receiving waters and develop a receiving water quality model to be used in the development of CSO Long Term Control Plans for participating members of the NJ CSO Group.

6.2 Compliance Monitoring Program Report

The Passaic Valley Sewerage Commission, as the lead organization of the NJ CSO Group, has submitted to the NJDEP the “NJ CSO Group Compliance Monitoring Program Report” (CMP Report), dated June 2018, to satisfy the requirements under NJPDES CSO Permit, Part IV, subpart Combined Sewer Management, Section D.3.d for the participating NJ CSO Group permittees, including the City of Elizabeth. The report summarizes the ambient in-stream sampling work and data collected under the Baseline Compliance Monitoring Program (BCMP) in support of the NJPDES CSO Permit compliance. The purpose of the BCMP is to generate sufficient data to establish existing ambient water quality conditions for pathogens in the CSO receiving waters and to update, calibrate and validate a pathogen water quality model of the receiving waterbodies. The work was conducted according to the Quality Assurance Project Plan (QAPP) prepared and submitted by PVSC to the NJDEP in December 2015, and approved by NJDEP upon revision in February 2016.

The CMP Report describes the full Baseline Compliance Monitoring Program implemented through the NJ CSO Group, including the program description; the field sampling and the field and laboratory analytical methods used; the data quality objectives; an evaluation of data completeness, precision, and representativeness; and presentations and discussion of data results. Certain information from the CMP Report is presented herein, as applicable to the

overall program and the City of Elizabeth and its CSO receiving waters. The reader can refer to the full CMP Report for further details on the Baseline Compliance Monitoring Program.

The BCMP involved 3 categories of data generation and collection, based on sampling location and sampling for routine or wet weather events:

- Baseline Sampling was modeled after and intended to supplement the approved routine sampling program of the New Jersey Harbor Discharges Group (NJHDG), of which PVSC is a member. The sampling frequency matched NJHDG, varying with time of year. A sampling frequency of twice a month was targeted in the spring months of May and June; weekly sampling conducted as possible during the summer months of July, August, and September; and monthly sampling was conducted in the 7-month period of October through April.
- Source Sampling targeted the major influent streams within the study area to establish non-CSO loadings and coincided with the NJHDG and Baseline Sampling. Baseline Sampling and Source Sampling stations were sampled under the same field activities.
- Event Sampling was timed to coincide with rainfall to capture three discrete wet-weather events over the course of the year on each segment of the NY-NJ Harbor complex impacted by CSOs.

The CMP Report organizes the baseline, source, and event sampling locations by waterbody grouping, station number, and specific waterbody. A total of 35 baseline sampling locations (including select NJHDG stations), 7 source sampling locations, and 25 event sampling locations (which overlap with certain baseline sampling locations) were incorporated in the BCMP. The overall plan of the sampling locations from the CMP Report is shown in Figure 6-1 at a reduced scale.

Figure 6-2 provides an enlarged plan of the BCMP ambient water sampling locations in and surrounding the City of Elizabeth and Table 6-1 tabulates certain information from the CMP Report for the 11 corresponding sampling stations.

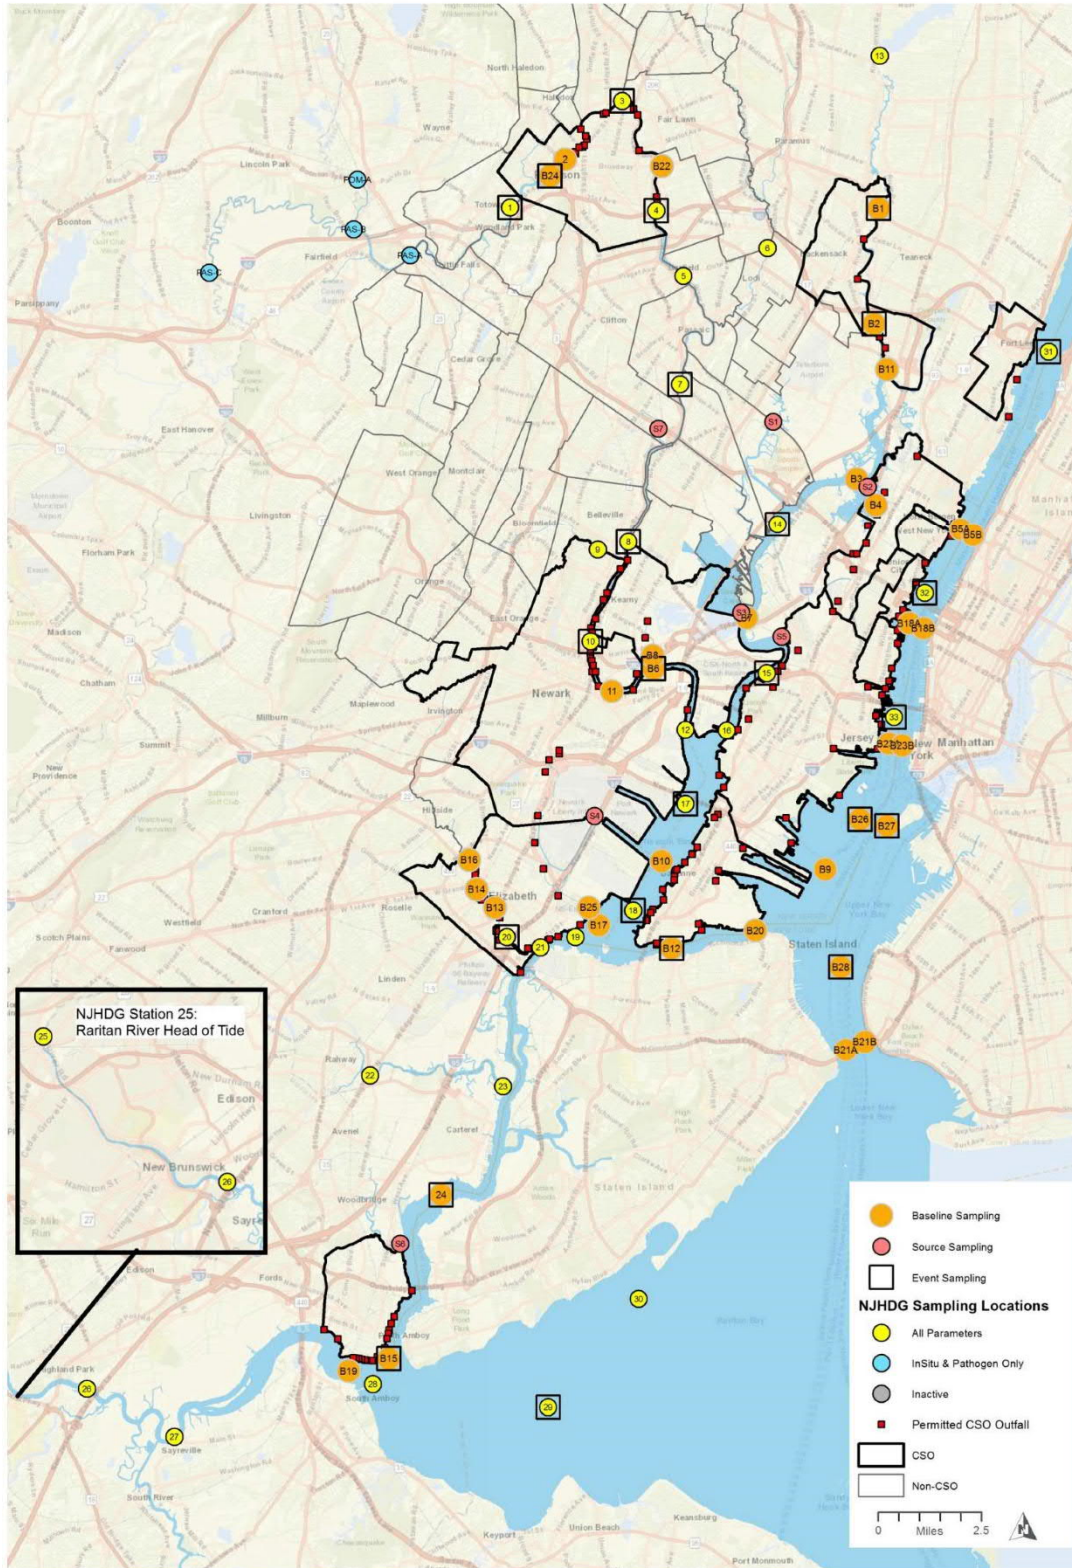

Table 6-1: Compliance Monitoring Program Sampling Locations, City of Elizabeth

Waterbody Grouping	Station No.	Waterbody	Sampling Category	Surface WQS Classification
Newark Bay & Tributaries	B10	Newark Bay	Baseline	SE3
	18	Newark Bay	NJHDG & Event	SE3

	S4	Peripheral Ditch	Source	SE3
	B25	Great Ditch Outlet	Baseline	SE3

Source: NJ CSO Group Compliance Monitoring Program Report, Passaic Valley Sewerage Commission, June 2018.

A total of 23 baseline and source (i.e., routine) sampling events were completed from April 2016 through March 2017 and the information presented for the baseline CMP Report includes the NJHDG data collected between March 2016 and December 2016. The event sampling goal of capturing 3 significant wet weather events, consisting of greater than 0.5 inches of precipitation within 24 hours, at each targeted station was completed across 4 sampling dates.

All samples collected were analyzed for fecal coliform and enterococcus and samples from freshwater locations were also analyzed for *E. coli*. During field sampling, field measurements were also made for: temperature, salinity, dissolved oxygen, light penetration (secchi depth), and turbidity. Depending on the sampling location, samples were collected at either 1 or 2 depths. For event sampling, locations were sampled twice per day for 3 days, except for 3 locations that were sampled 4 times per day for 3 days.

Regarding data completeness, the CMP Report notes that 1 baseline/source sample at Location S4, Peripheral Ditch, was not collected during the week of July 5, 2016 due to site access difficulties; 2 wet weather event samples (associated with 1 collection time for 2 depths) at Location 18, Newark Bay, were not collected the week of January 24, 2017 due to high winds; 1 event sample from Location 20, Elizabeth River, for the week of January 24, 2017 was not analyzed due to a bottle break; and 1 event sample from Location 20, Elizabeth River, on June 8, 2016 was not analyzed for fecal coliform due to a laboratory accident. For the overall program, the number of targeted samples collected and analyzed for baseline/source sampling and event sampling was 99.4% and 97.8% respectively.

6.3 Compliance Monitoring Program Ambient Water Quality Results

The Compliance Monitoring Program Report presents the ambient water quality data collected under the program as 6-panel time series plots of temperature, salinity, Secchi depth / turbidity, fecal coliform, enterococcus, and *E. coli* for each sampling location, ordered spatially by waterbody and generally proceeding upstream to downstream. The graphs are labeled with a waterbody grouping, specific waterbody name, sampling station (i.e., location) number, and waterbody classification.

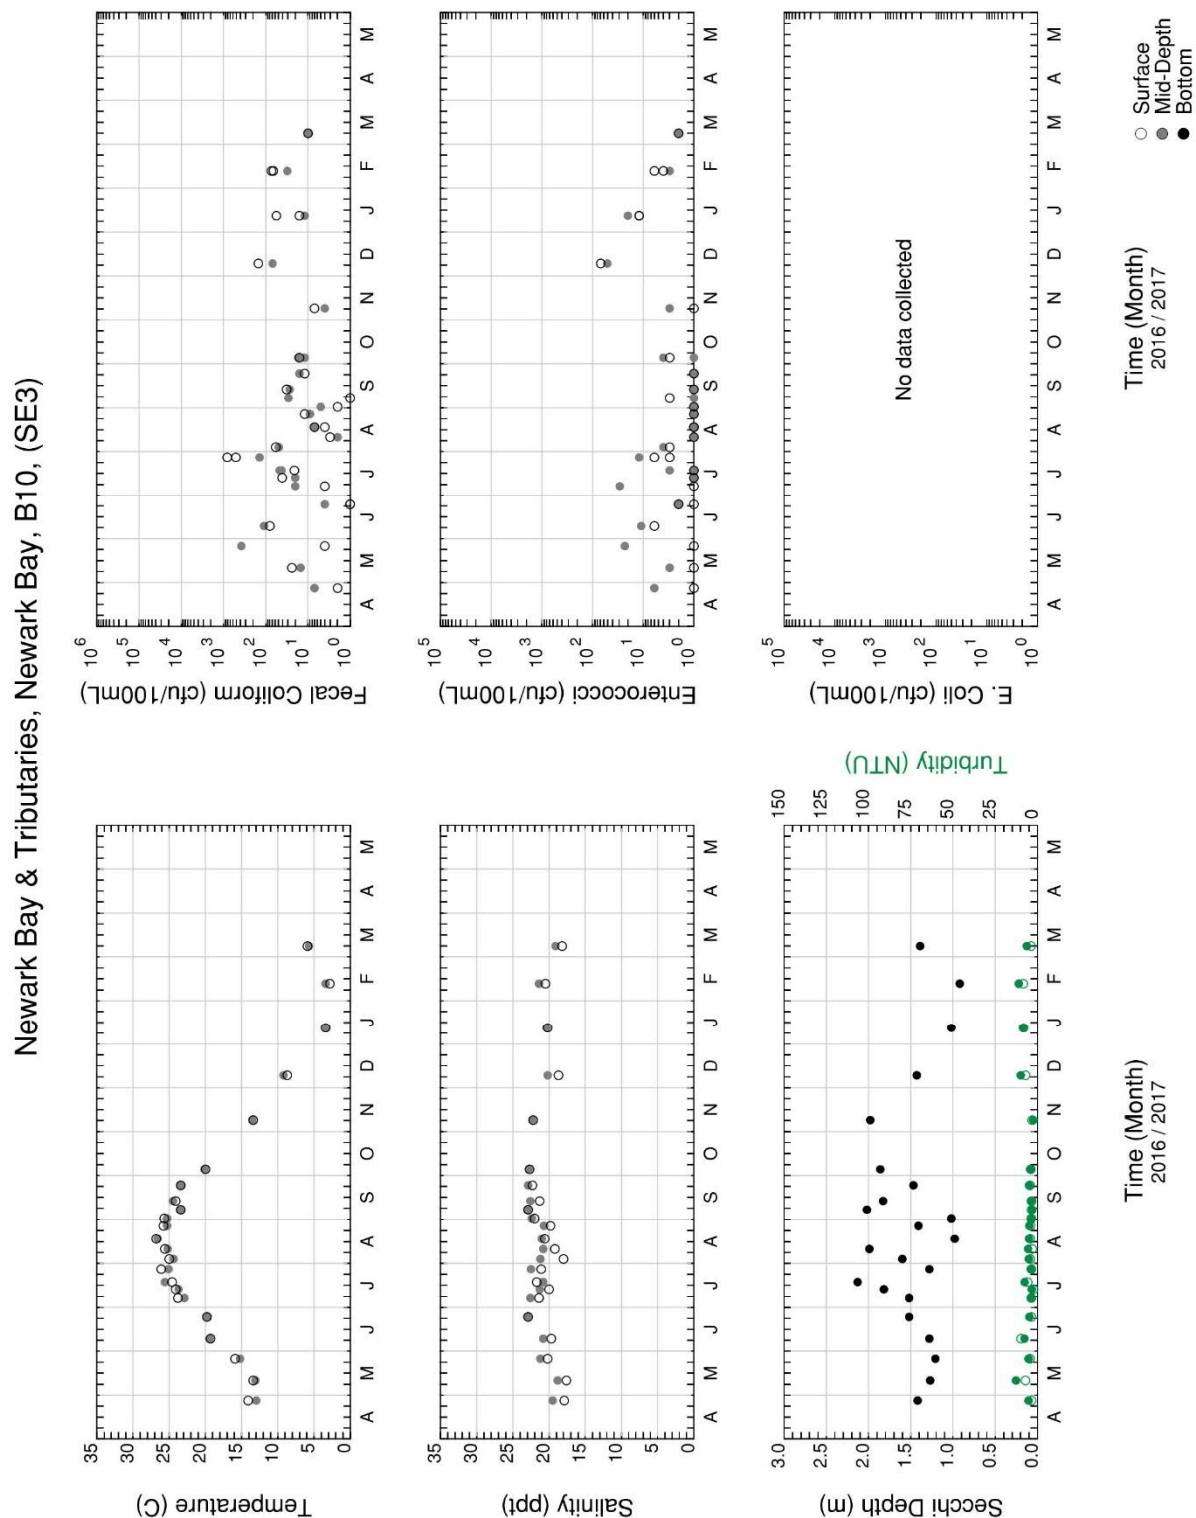

6.3.1 Baseline and Source Sampling Water Quality Results

Excerpts of the baseline and source sampling data graphs given in the CMP Report for the sampling locations in or near the City of Elizabeth are reproduced below in the following figures:

- Figure 6-3: Baseline and Source Sampling Results, Station B10
- Figure 6-4: Baseline and Source Sampling Results, Station 18
- Figure 6-5: Baseline and Source Sampling Results, Station B17

- Figure 6-10: Baseline and Source Sampling Results, Station B13
- Figure 6-11: Baseline and Source Sampling Results, Station 20
- Figure 6-12: Baseline and Source Sampling Results, Station S4
- Figure 6-13: Baseline and Source Sampling Results, Station B25

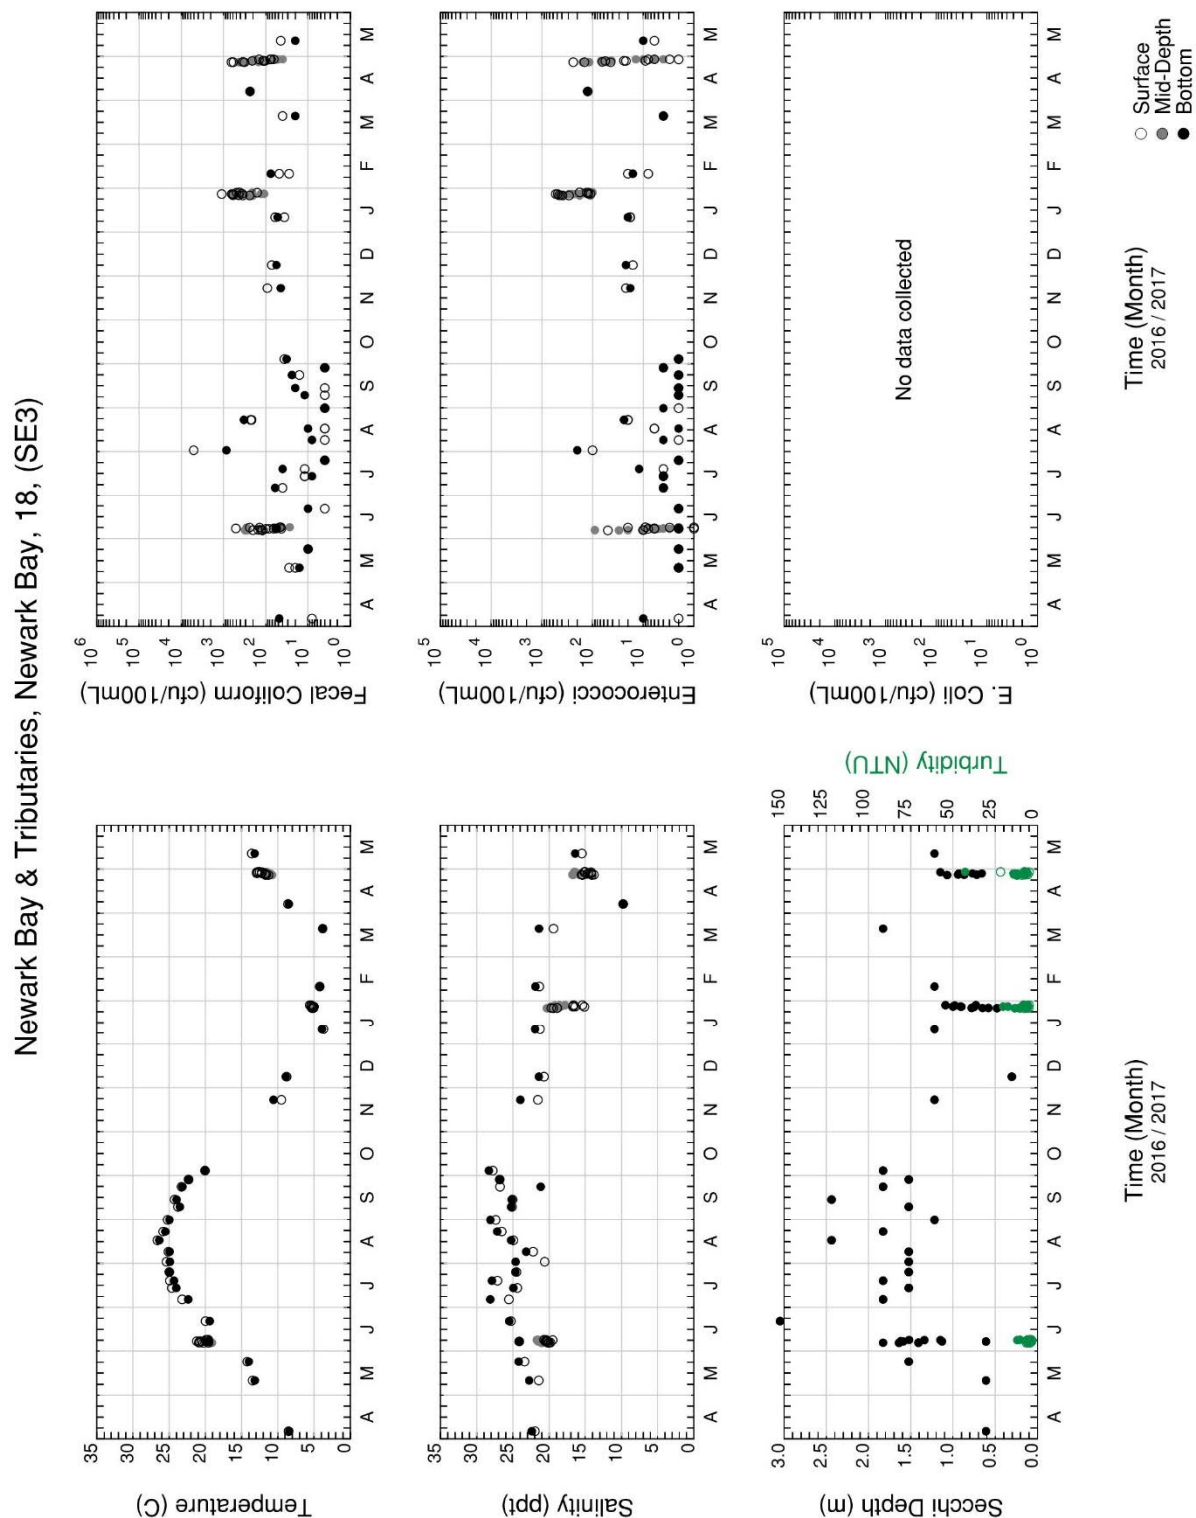

The graphs from the CMP Report show the available receiving water data collected by PVSC and its consultants under the program from April 2016 to March 2017 and the NJHDG data collected from March 2016 to December 2016. On these plots, data are presented as open circles for surface data, filled gray circles for mid-depth data, and filled black circles for bottom data. Secchi depth does not fall into a specific depth category, but is plotted with filled black circles. Turbidity is shown on the same panel as Secchi depth and is presented with filled green circles.

6.3.2 Wet Weather Event Sampling Water Quality Results

Excerpts of the wet weather event data graphs given in the CMP Report for the sampling locations in and near the City of Elizabeth are reproduced below in the following figures:

Figure 6-14: Wet Weather Event Sampling Results, Station 18, June 6-8, 2016

Figure 6-15: Wet Weather Event Sampling Results, Station 20, June 6-8, 2016

Figure 6-16: Wet Weather Event Sampling Results, Station 20, January 4-6, 2017

Figure 6-17: Wet Weather Event Sampling Results, Station 18, January 24-26, 2017

Figure 6-18: Wet Weather Event Sampling Results, Station 20, January 24-26, 2017

Figure 6-19: Wet Weather Event Sampling Results, Station 18, April 26-28, 2017

The graphs from the CMP Report show the available receiving water data collected by PVSC and its consultants for 4 wet weather sampling events, commencing respectively on June 6, 2016, January 4, 2017, January 24, 2017, and April 26, 2017. The plots are shown on a 3-day timescale.

Data collected during these events were meant to assess the trend of bacteria concentrations after a wet-weather event for the purposes of water quality modeling. On these plots, data is presented as color-coded circles, with darker tones representing surface data and lighter tones representing mid-depth and bottom data. Secchi depth does not fall into a specific depth category, but is plotted with filled circles. Turbidity is shown on the same panel as Secchi depth and is presented with filled triangles following the same light/dark tone.

6.3.3 Analysis and Discussion

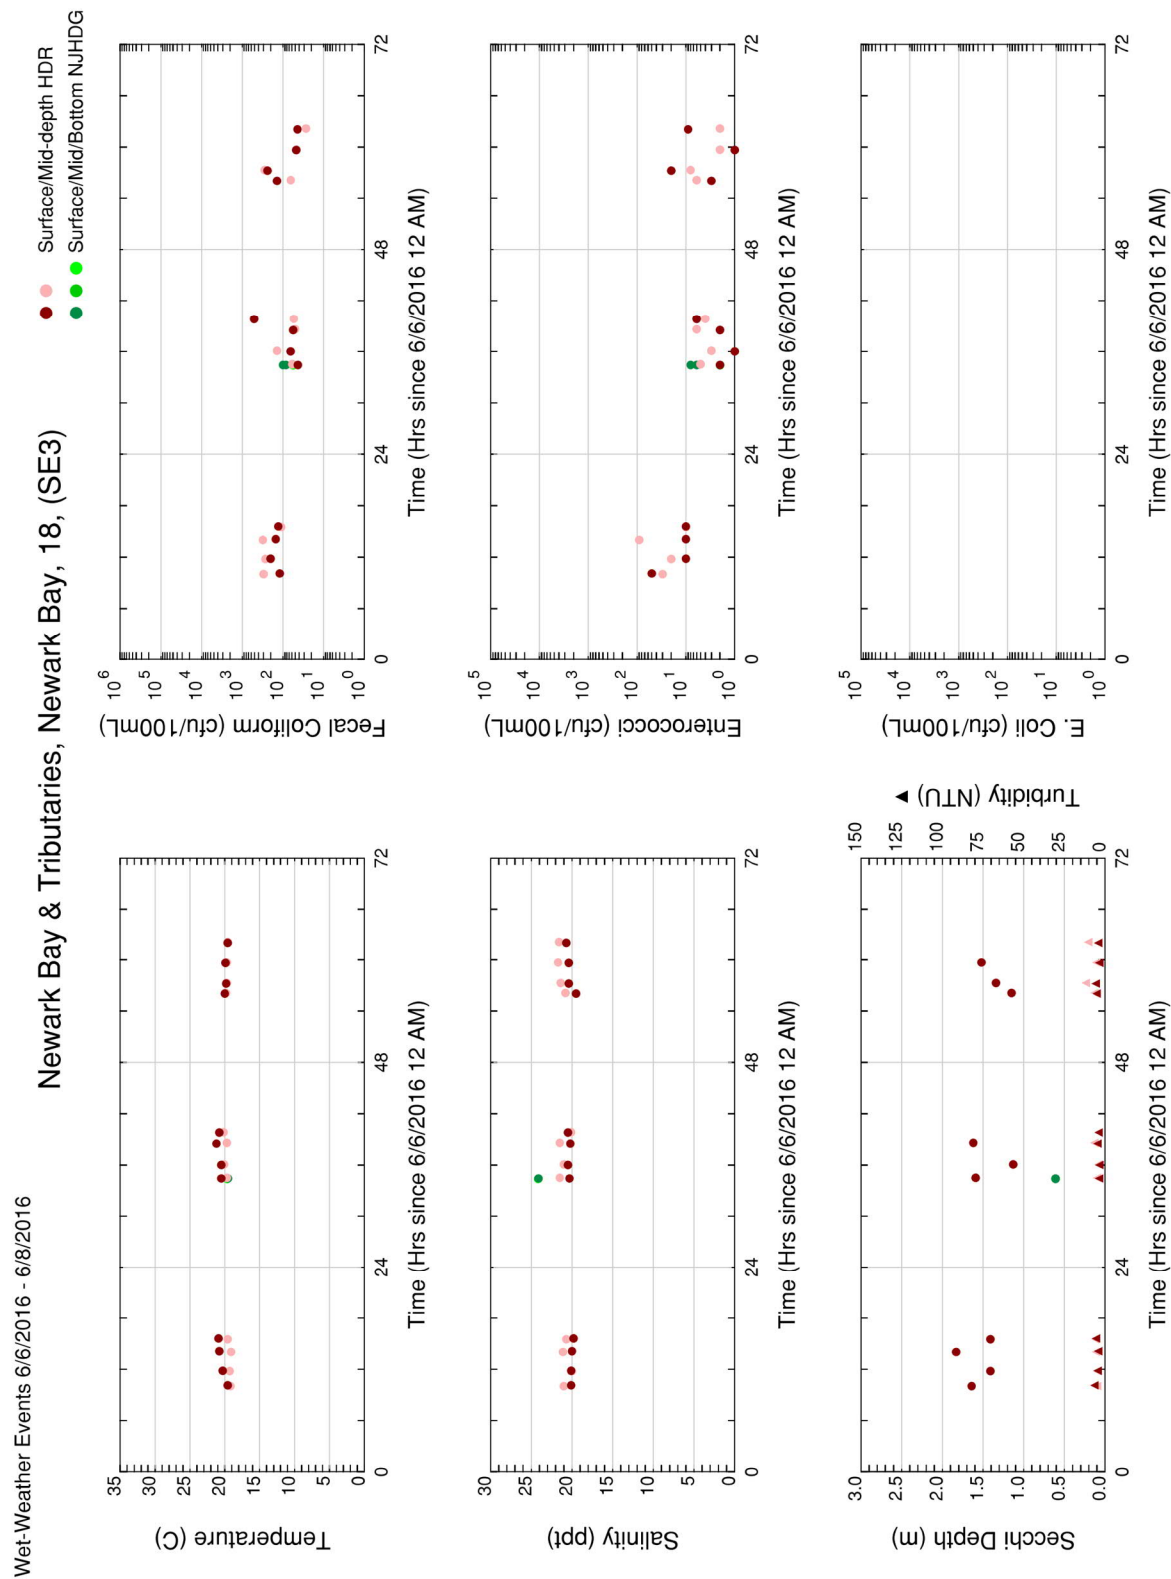

As stated in the NJ CSO Group CMP Report, the baseline ambient monitoring data collected meets the goals of the corresponding Quality Assurance Project Plan and the data is sufficient for calibrating the pathogen water quality model that is being developed. Assessment of the data quality will continue through the model calibration process.

State WQS related to pathogens are based on a monthly geometric mean value for a minimum of 5 samples in a 30-day period. Table 6-2 indicates the New Jersey Surface Water Quality Standards designated use and bacterial quality criteria for the classifications of the Elizabeth CSO receiving waters.

Table 6-2: Bacterial Water Quality Standards for Receiving Waters

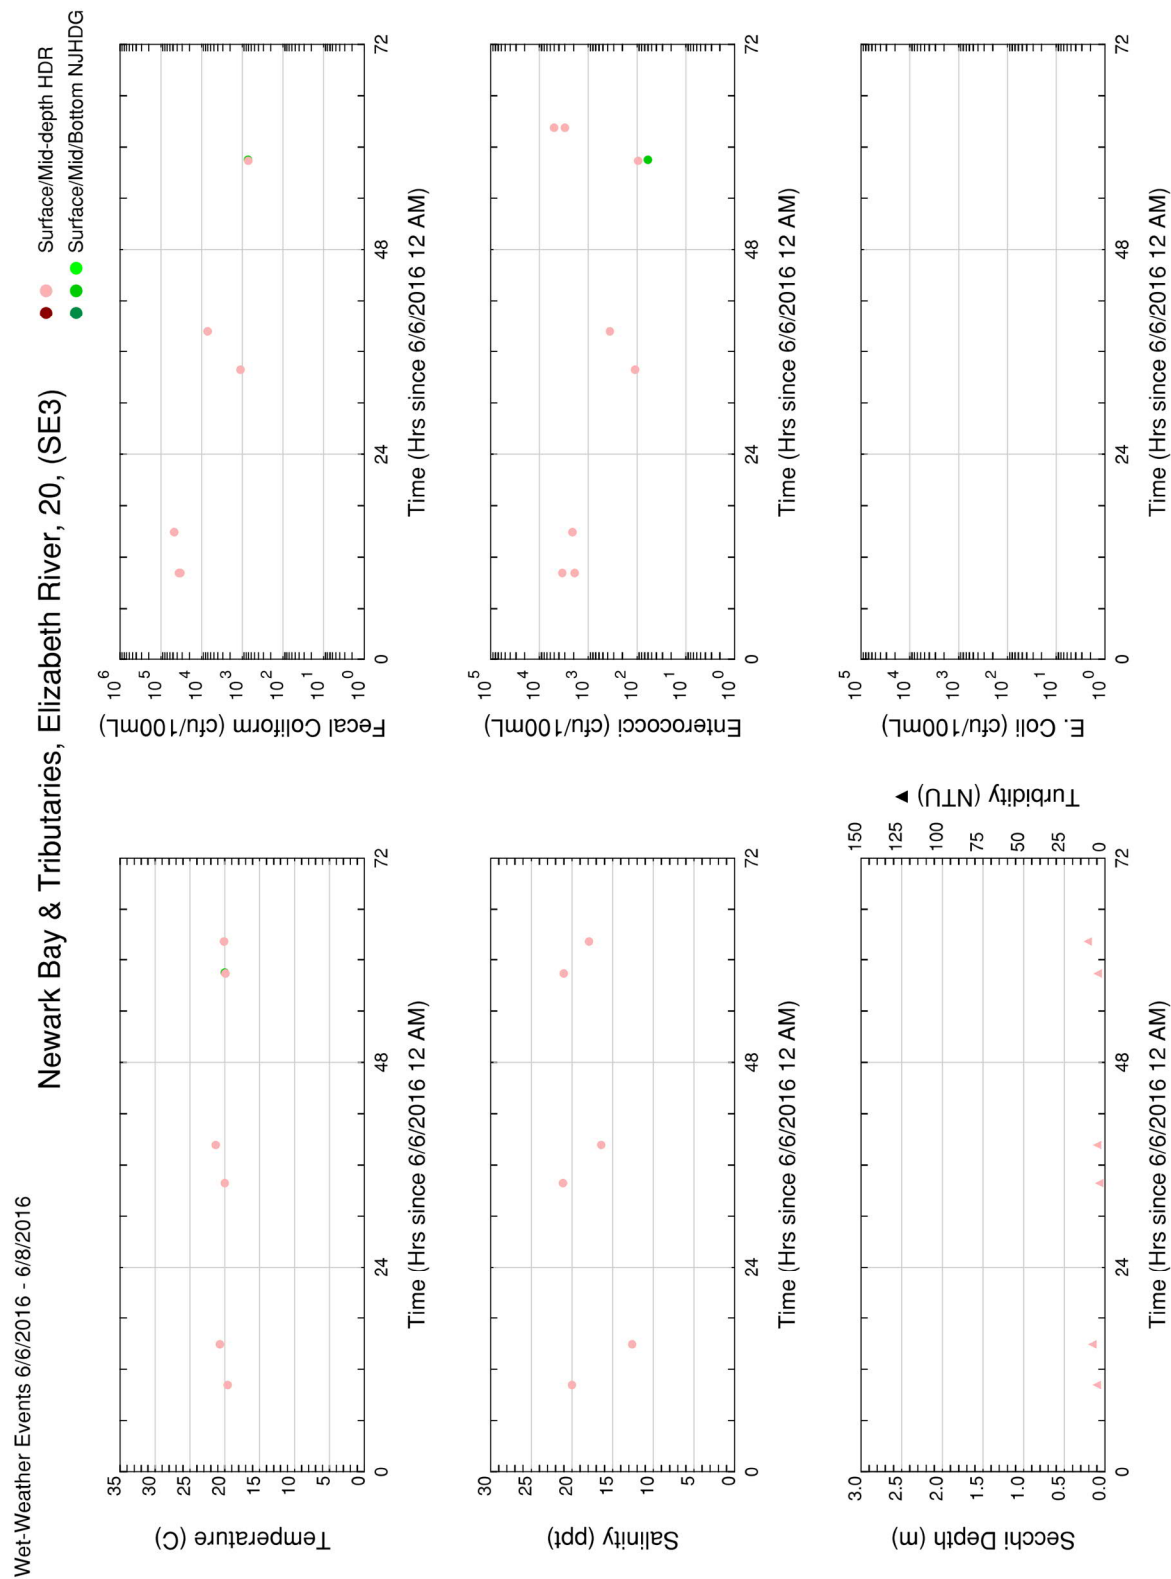

Waterbody	Surface WQS Class	Bacterial Standard (counts/100 ml)			Highest Designated Use	
		Indicator	Geometric Mean	Single Sample Maximum	Recreational	Other
Elizabeth River, north of Broad St. bridge	FW2-NT	E. coli	126	235	Primary	Public water supply
Elizabeth River, Broad St. bridge to mouth	SE3	Fecal coliform	1,500	not appl.	Secondary	Diadromous fish migration
Newark Bay						
Arthur Kill

Source: NJ CSO Group Compliance Monitoring Program Report, Passaic Valley Sewerage Commission, June 2018.

The CMP Report notes that the ambient in-stream monitoring conducted under the program was not intended to provide an adequate data volume for assessing attainment of pathogen water quality standards. However, the following general assessments on the likelihood of attainment are made in the report:

- The lower regions of the Passaic and Hackensack Rivers appear likely to violate existing water quality criteria, but attainment appears to improve closer to Newark Bay.
- The larger waterbodies (i.e., Newark Bay, Hudson River, Arthur Kill, Kill Van Kull) appear to meet existing water quality criteria. Newark Bay and the Kills are primarily SE3 waterbodies, while Raritan Bay is subject to more stringent shellfishing water quality standards.
- Several smaller riverine waterbodies appear unlikely to meet attainment. This includes the Rahway River, Saddle River, Second River, and Elizabeth River. The Raritan River may also have attainment issues.
- Many rivers without CSOs have high bacteria loads. Data collected at source sampling locations indicate non-attainment of waters entering the Passaic and Hackensack Rivers, contributing pollutant loads into the study area from areas that do not have CSOs.

Furthermore, the baseline ambient pathogen monitoring data appears to be consistent with prior water quality reporting by the New Jersey Harbor Dischargers Group, which has noted similar indications of possible pathogen WQS attainment in Newark Bay, Arthur Kill, and Kill Van Kull, whereas higher fecal coliform and enterococcus concentrations have been observed in smaller tributaries like the Elizabeth River and Rahway River to the Arthur Kill and the Second River and Saddle River to the Passaic River.

In viewing the CMP Report graphs for the baseline sampling results, the data indicates that the Elizabeth River waters entering the City likely do not meet WQS for pathogens. Furthermore, no changes in the pathogen data ranges are discernable between sampling locations situated along the stretch of the Elizabeth River studied. Values for sampling stations located along the upstream sections of the river are generally similar to values for stations along the downstream sections. As the number of CSO outfalls tributary to the river increase further downstream, the ambient in-stream monitoring data does not demonstrate a direct relationship between baseline pathogen concentrations and the presence of tributary CSO outfalls.

In comparing baseline and wet weather event sampling results for a given location, the wet weather pathogen concentrations fall within the upper range of the observed baseline ambient water quality results. However, it should be recognized that combined sewer overflows are only one of many wet weather pollution sources that may be influencing the higher in-stream pathogen concentrations coincident with the wet weather event sampling data and the contribution of the other pollution sources must be evaluated.

6.4 Pathogen Water Quality Model

The City of Elizabeth is a participating member of the NJ CSO Group involved in the development of a Pathogen Water Quality Model (PWQM) for consideration in the CSO LTCP alternatives selection and Compliance Monitoring Program. The PWQM is being developed to supplement ambient in-stream pathogen monitoring under the baseline CMP and facilitate the evaluation of CSO control approaches and alternatives. Water quality data collected under the baseline CMP and system characterization work is being used to calibrate and validate the PWQM.

On behalf of the NJ CSO Group permittees, PVSC submitted a Quality Assurance Project Plan for the PWQM to the NJDEP for review, which was approved upon revision in February 2017. As part of this effort, an existing Harbor Estuary Program (HEP) Pathogen Total Maximum Daily

Load (TMDL) model is being modified, updated, recalibrated, and revalidated by consultants employed by PVSC to serve the current proposed use of CSO LTCP development by the NJ CSO Group members in the New York-New Jersey Harbor complex. The modeling QAPP discusses data reliability, calibration methods, basis of input loads, and other information pertinent to supporting the proposed model enhancements necessary for the CSO program.

As described in the QAPP, the PWQM is a computational model of the receiving waters that may be used to simulate bacteria concentrations in the waters of the harbor complex under existing conditions and to assess the attainment of applicable water quality standards under potential future conditions. The previously developed HEP pathogen model will be the platform for the model refinement. The HEP model consists of two major components: a hydrodynamic module that defines the transport of the estuarine water throughout the Harbor-Bight-Sound complex, and a water quality module that tracks the fate of contaminants and by-products (such as bacteria) in the water column. The water quality component of the HEP model has been appropriately modified to track the fate of pathogen bacteria indicators by incorporating sewer system model calculated outputs of CSO and stormwater discharges as inputs, along with boundary tidal, flow, and meteorological conditions to project varying pollutant concentrations spatially, vertically, and temporally. The previous HEP modeling approach was reviewed by a model evaluation group (MEG) comprised of independent modeling experts and a similar MEG is being assembled per the current model QAPP.

For the PWQM, the previously calibrated and validated hydrodynamic and water quality modules will be updated and enhanced to meet present water quality modeling standards and current modeling objectives. The PWQM is intended to function as a validated tool that reasonably replicates the observed timing, duration, and magnitude of ambient pathogen data in the study area and that is capable of simulating pathogen water quality conditions for varying CSO strategies to assist in assessing the CSO impacts on ambient pathogen water quality.

The NJDEP approved Pathogen Water Quality Model QAPP can be referenced for further details on the model development scope, methodologies, and management activities.

7 Consideration of Sensitive Areas

7.1 Background

The following conditions regarding the consideration of sensitive areas are contained in the NJPDES CSO Permit, Part IV, subpart Combined Sewer Management:

- Section D.3.b.iv states that in accordance with Section G.3, the permittee shall submit the Consideration of Sensitive Areas Information of the LTCP within 36 months of the effective date of the permit (EDP), which corresponds to a due date of July 1, 2018.
- Section G.1.d.ii indicates that for the sewer system characterization, the permittee shall evaluate information necessary to understand the number, location, and frequency of overflows and their location relative to sensitive areas.
- Section G.1.d.v states that the permittee shall identify sensitive areas where CSOs occur. These areas include designated Outstanding National Resource Waters, National Marine Sanctuaries, waters with threatened or endangered species and their habitat, waters used for primary contact recreation (including but not limited to bathing beaches), public drinking water intakes or their designated protection areas, and shellfish beds.
- Section G.3 notes that the permittee's LTCP shall give the highest priority to controlling overflows to sensitive areas, in accordance with D.3.a and G.10, and that the LTCP is to:
 - Prohibit new or significantly increased CSOs to sensitive areas.
 - Eliminate or relocate CSOs that discharge to sensitive areas wherever physically possible and economically achievable, except where elimination or relocation would provide less environmental protection than additional treatment.
 - Where elimination or relocation is not physically possible and economically achievable, or would provide less environmental protection than additional treatment, the permittee shall provide the level of treatment for remaining CSOs deemed necessary to meet water quality standards for full protection of existing and designated uses.
- Section G.4.b indicates that the Evaluation of Alternatives Report is to enable the permittee to select the alternatives that give the highest priority to controlling CSOs to sensitive areas.
- Section G.8.c notes that the implementation schedule of the LTCP shall consider CSO overflows that discharge to sensitive areas as the highest priority.

These conditions are consistent with the requirements of the National CSO Control Policy established by United States Environmental Protection Agency (EPA) and emphasize EPA's expectation that permitting strategies place the highest priority on controlling overflows to sensitive areas. Information on the identification of sensitive areas within the City of Elizabeth and an assessment of the potential need for higher prioritization of any specific CSO discharge location is presented below.

7.2 NJ CSO Group Regional Assessment

The City of Elizabeth is participating as a member of the NJ CSO Group, which has prepared an assessment of sensitive areas for the study area associated with the receiving and adjacent downstream waters that may be potentially affected by discharges from the pertinent NJ CSO Group combined sewer service areas. The report entitled "Identification of Sensitive Areas Report", dated June 2018, has been submitted by the Passaic Valley Sewerage Commission, on behalf of participating permittees, to the NJDEP separately and is included herein by reference.

The overall findings and conclusions from the consideration of sensitive areas for the NJ CSO Group region described in the report are:

- A comprehensive review of online databases, correspondence with regulatory agencies, direct observations and local environmental organizations was conducted to identify potential sensitive areas impacted by CSOs within the study area.
- There are no Outstanding Natural Resource Waters or National Marine Sanctuaries in the study area.
- There were no sensitive areas identified as it is related to waters with threatened or endangered species or their habitats.
 - The US Fish and Wildlife Service (USFWS), National Oceanic and Atmospheric Administration (NOAA), New Jersey Natural Heritage Program (NJNHP), and NJDEP Division of Fish and Wildlife were contacted regarding endangered or threatened species which potentially could live in the project area. All species listed by USFWS are included in the State lists.
 - While areas that may have endangered or threatened species potentially present during parts of the year were identified, determinations from the USFWS and NJDEP found no critical habitats in the study area for Federal or State listed threatened or endangered species.
 - No threatened or endangered species identified on the NOAA maps has been confirmed to live, eat, or breed near a CSO in the study area.
 - The endangered Atlantic and shortnose sturgeon populations cited in the study area have been recovering since the 1970s, and are stabilizing at rates suggesting the current protections for water quality are sufficient, and not impacted by CSOs.
- No primary contact recreation was observed or reported within the study area and no sensitive areas related to primary contact recreation were identified.
- No sensitive areas were determined based on the proximity of public drinking water intakes or their designated protection areas.
- No sensitive areas due to shellfish beds were found to be applicable as the only commercial shellfish harvesting area operating within the study area is a restricted zone in the Raritan Bay and it is separated by a few miles from the nearest study area CSO.

7.3 Additional Consideration

Information on sensitive areas specific to the City of Elizabeth location has also been considered and is presented below. This further evaluation served to verify and support the NJ CSO Group regional assessment. The analysis of sensitive areas for the City of Elizabeth CSO receiving waters is based on the criteria of the EPA National CSO Policy and NJPDES CSO Permit, which defines sensitive areas as including:

- Outstanding National Resource Waters
- National Marine Sanctuaries
- Waters with threatened or endangered species and their habitat
- Waters with primary contact recreation
- Public drinking water intakes or their designated protection areas
- Shellfish beds

7.3.1 Outstanding National Resource Waters

Outstanding National Resource Waters is the first and most protective tier of water resources antidegradation protection. Per NJDEP surface water quality standards regulations, Outstanding National Resource Waters include surface waters classified as Freshwater 1 (FW1) or Pinelands (PL). The second tier of antidegradation designation is Category One (C1) waters, which are designated through rulemaking for protection from measurable changes in water quality because of their Exceptional Ecological Significance, Exceptional Water Supply, Exceptional Recreation, and Exceptional Fisheries to protect and maintain their water quality, aesthetic value, and ecological integrity. Based on available NJDEP GIS data and related environmental data, none of the City of Elizabeth CSO outfalls discharge to FW1 waters (also known as non-degradation waters), Pinelands (PL) waters, or Category 1 waters.

The Nationwide Rivers Inventory (NRI) is a listing maintained by the National Parks Service of more than 3,400 free-flowing river segments in the United States that are believed to possess one or more outstandingly remarkable natural or cultural values judged to be of more than local or regional significance. It includes about 67 New Jersey river sections, at approximately 490 river miles. None of the City of Elizabeth CSO outfalls discharge to these rivers or river sections.

7.3.2 National Marine Sanctuaries

National Marine Sanctuaries are federally designated of special national significance due to its resource or human-use values. An office of the National Oceanic and Atmospheric Administration manages a system of protected marine water that includes 13 national marine sanctuaries. None are located in New Jersey; the closest location is Stellwagen Bank, off the coast of Massachusetts.

7.3.3 Waters with Threatened or Endangered Species and Their Habitat

Federal and State listed threatened and endangered species existing in the City were evaluated based on information available from the NJDEP Natural Heritage Program and the Landscape Project database for Piedmont Plains area. No Natural Heritage Priority Sites, which represent critically important areas for rare plants and ecological communities, are present in the City or in the waterbodies to which the City of Elizabeth CSO outfalls discharge.

Regarding fish and aquatic wildlife species, the Arthur Kill and Newark Bay are included as migration corridors in the range for the Atlantic sturgeon (*Acipenser oxyrinchus oxyrinchus*) and the shortnose sturgeon (*Acipenser brevirostrum*), which are both listed as Federal and State endangered species. Both the Atlantic and shortnose sturgeon migrate between fresh and saltwater. In the New Jersey area, the Atlantic sturgeon is mainly found in the Delaware River, Delaware Bay, and the Atlantic Ocean. It may also be found in the Hudson River. However, Atlantic sturgeon larvae and eggs are not encountered within the New Jersey portion of the Hudson River as Atlantic sturgeon populations in the Hudson River spawn in the river freshwaters of upstate New York.

Shortnose sturgeon spawn and remain in freshwater for most of its life cycle, but spends some time in estuary waters as it migrates. The primary region for New Jersey's shortnose sturgeon is the upper tidal Delaware River, but it also may be found in the Hudson River. Shortnose sturgeon larvae and eggs also are not encountered within the New Jersey portion of the Hudson River as these populations spawn in the river freshwaters of upstate New York. Furthermore, this species does not migrate until it has reached adult size, typically when it is between 3 to 10 years old.

Atlantic and shortnose sturgeon populations were historically impacted by overfishing. Relative to pollution risks, contamination from endocrine disrupting chemicals, like PCB, pesticides, dioxins, mercury, and cadmium, may pose the most serious risk to the sturgeon species. These contaminants have been linked to reduced fertility, increased larvae and juvenile mortality, and other reproductive problems. Other threats include river dredging, habitat degradation, boat and ship strikes, unwanted catch during commercial and recreational fishing, and poaching.

The influence of CSO discharges on any potential presence of sturgeon species in the City of Elizabeth receiving waters is likely insignificant, particularly given their life cycle, migration behavior, and waterway use, and the impacts from other pollution sources and environmental threats. Spawning does not occur within these receiving waters and the Arthur Kill and Newark Bay are not considered customary waters for either species. In fact, the NJDEP Division of Fish & Wildlife research on Atlantic sturgeon has focused on the Delaware Bay with the deployment of acoustic telemetry receivers for movement detection, while New York State has studied juvenile Atlantic sturgeon populations in the Upper New York Bay and the movement of the fish along the Hudson River in that state. Atlantic and shortnose sturgeon might migrate through the Arthur Kill and Newark Bay between spawning habitats, but do not inhabit the area. Furthermore, a migratory corridor for sturgeon would apply broadly to the Elizabeth CSO discharge points, which prevents prioritizing specific locations for CSO control in this area.

As noted in the NJ CSO Group Identification of Sensitive Areas Report, Atlantic and shortnose sturgeon populations in the Hudson River area have been recovering since the 1970s, and are stabilizing at rates suggesting the current protections for water quality are sufficient. A literature review found no specific evidence of negative impacts from human pathogens on sturgeon groups and salinity, river flow, depth and use of deep channel waters make extended exposure to human pathogens from nearshore and intermittent CSO discharges unlikely. Studies also indicate that the adult shortnose sturgeon population has increased at a rate higher than expected, with good size growth in marked specimens.

The NJDEP Landscape Project dataset queries for species based habitat patches also indicate that various bird s and a butterfly species listed as threatened or endangered may be present within the municipal boundary. As non-aquatic wildlife, the populations and habitats for these species are not likely impacted by wet weather overflow discharges. Determinations by Federal and State regulators also found no critical habitats associated with these species in the NJ CSO Group study area. Moreover, identification of higher priority discharge locations for any birds and insects is not applicable given the broad roaming area and unlimited movement of these species across the study area.

7.3.4 Primary Contact Recreation Waters

NJDEP Surface Water Quality Standards regulations, N.J.A.C. 7:9B-1.4 defines “Primary contact recreation” as water-related recreational activities that involve significant ingestion risks and includes, but is not limited to, wading, swimming, diving, surfing, and water skiing.

Any existing primary contact recreation use of the subject receiving waters is unusual and rare. There are no bathing beaches present in the area and no primary contact recreation use has been observed or reported. Public access is limited and CSO outlets are situated along heavily developed urban or disturbed sites. The channelized portion of the Elizabeth River upstream of South Broad Street is designated as FW2-NT(C2), which refers to Category 2 non-trout freshwater, but there is no existing primary contact use as there is no access to the water, the channel is fenced in and has a concrete base and walls, and the water is shallow. Furthermore, heavy container ship and barge traffic on the Arthur Kill and Newark Bay make these receiving waters non-conducive to primary contact recreation or other activities such as kayaking,

canoeing, or jet skiing. Given the extensive service of the waterways for marine shipping and commercial navigation, swimming beaches, primary contact recreation, and other contact uses would likely not be encouraged as the large commercial vessel and boat traffic would endanger swimmers and kayakers.

7.3.5 Public Drinking Water Intakes or their Designated Protection Areas

Based on available NJDEP GIS data, no surface water intake for public drinking water or associated designated protection area exists in the vicinity or downstream of the City CSO discharge points. A small portion of a Tier 3 (12-year) community groundwater well head protection area occurs along the boundary with the Borough of Roselle, but it does not coincide with any CSO discharge location or receiving water. Therefore, the well should not be affected by CSO discharges.

7.3.6 Shellfish Beds

Per the NJDEP shellfish waters classification rules codified under N.J.A.C. 7:12, NJDEP classifies waters within the State for the purpose of shellfish harvest and use as either Prohibited, Restricted, Conditionally Restricted, Conditionally Approved, or Approved and delineates the boundaries of such waters. N.J.A.C. 7:12-2.1(a) prohibits shellfish harvesting in the waters of the northern New Jersey area, described as all the waters lying west and north of Raritan Bay, including the Raritan River, Arthur Kill, Kill Van Kull, Newark Bay, Passaic River, Hackensack River, Upper Bay, Hudson River and tributaries.

As such, no City receiving waters are designated for shellfish harvesting.

7.4 Supplemental CSO Team Input

In accordance with the NJPDES CSO Permits, the City of Elizabeth and JMEUC have invited members of the affected public to participate in a Supplemental CSO Team, which has been formed to solicit input and share information on the LTCP development process. Information on the sensitive areas assessment was compiled and presented to the Supplemental CSO Team at multiple meetings. The City and JMEUC sought input from the team on sensitive locations, particularly related to primary contact recreational and public use activities. The Supplemental CSO Team agreed that while jet skiing and kayaking have been occasionally observed on the Arthur Kill, such activities are uncommon. No wading, swimming, or other primary contact recreation activities in the receiving waters was reported.

The Supplemental CSO Team generally indicated that areas around the CSO discharge points are not accessible to the public and would be unsafe for contact recreational use. Members noted that fishing occurs along the Arthur Kill and Newark Bay off the piers at Slater Park and Veterans Memorial Waterfront Park and that the Elizabeth Municipal Marina along the Arthur Kill serves numerous small pleasure boats. While important public uses, fishing and boating are considered secondary contact recreational activities and are not identified as sensitive area attributes.

When asked, the Supplemental CSO Team concurred that no specific location of CSO discharge appears to be of more prominence, greater concern, or higher ecological or recreational value than other locations.

7.5 Summary

As a result of this information, the City has determined that no sensitive areas requiring elevated or accelerated CSO controls exist within its receiving waters and community. This is based on the following:

- Overall, there are no exceptional water quality elements or uses within the municipality that would distinguish any CSO outfall discharge area as more critical or of greater concern than other discharge areas.
- None of the City CSO receiving waters have been designated as outstanding national or state water resources.
- CSO discharge points are inaccessible to the public and located along heavily developed urban or disturbed sites, such as concrete floodwalls, earthen flood control levees, piers, and riprap shorelines. The discharge locations do not constitute undisturbed aquatic habitats.
- The waterway configurations and site development in the vicinity of the CSO discharge points were not intended and are not considered safe for primary contact recreation uses. The channel depths, flows, construction, and current prevailing uses deter full or partial body contact recreation in the receiving waters. Existing use for water recreation activities like jet skiing and kayaking are occasional and unusual.
- Determinations received from Federal and State wildlife agencies found no critical habitat present for Federal and State listed threatened and endangered species in the project area.
- Use of the City CSO receiving waters by the endangered Atlantic and shortnose sturgeon is only as a possible migration corridor and the Arthur Kill and Newark Bay historically did not support sturgeon populations and are not expected to support the species. Environmental contamination from endocrine disrupting chemicals have been linked to reproductive problems for the species and other threats from human activities have been noted, while the potential threat posed by the CSOs to migrating sturgeon is considered small, if any.
- No public drinking water intake, their designated protection areas, or shellfish beds are impacted by the Elizabeth CSO discharges.

8 Characterization of System Performance

In this section, the analysis conducted by the NJ CSO Group for the typical hydrologic year selection is discussed and the results from the calibrated and validated numerical model representing the existing Elizabeth combined sewer system is presented for this typical year hydrologic dataset. The frequency, volume, and duration of overflows at the CSO outfall locations have been calculated on a system-wide basis by continuous simulation using the collection system modeling application with the selected representative year precipitation record. Continuous simulation modeling involves using longer term precipitation periods rather than records for individual storms so that the effects of different storm sequence patterns within an average year are considered.

8.1 Typical Hydrologic Year Selection

To accurately characterize the annual average existing system overflow performance, it is necessary to review historical rainfall data and gain an understanding of local average storm patterns. The selection of a typical hydrologic record serves to provide a representative and unbiased prediction of average design rainfall conditions that incorporates the variability observed in the historical records. The National CSO Control Policy from the EPA recommends that CSO control alternatives be assessed on a “system-wide, annual average basis”. This is accomplished by continuous simulation using a typical hydrologic period for the combined sewer system and receiving water quality modeling applications. The CSO Policy supports continuous simulation modeling, i.e., using long term precipitation records rather than records for individual storms. Long term continuous precipitation records enable model simulations to be based on a sequence of storms so that the additive effect of storms occurring close together can be examined, as well as having storms with a range of characteristics.

On behalf of the participating NJ CSO Group permittees, the Passaic Valley Sewerage Commission (PVSC) prepared and submitted to the NJDEP a document titled “Typical Hydrologic Year Report”, dated May 2018. The report describes the methodology utilized, the results from the statistical and ranking studies performed, and the hydrologic period recommended for use by the NJ CSO Group permittees in the development of the respective CSO Long Term Control Plans. As NJ CSO Group permittees, the City of Elizabeth and JMEUC concurred with the selection of 2004 as the recommended typical year hydrologic dataset for its LTCP efforts. The NJDEP responded in May 2018 that the submitted report addressed all its questions and comments to its satisfaction. The NJ CSO Group Typical Hydrologic Year Report and the corresponding NJDEP determination letter are incorporated in Appendix I.

The NJ CSO Group obtained hourly and daily precipitation data from the National Oceanic and Atmospheric Administration (NOAA) gauge at Newark Liberty International Airport for analyzing individual rainfall events, event characteristics, and annual and seasonal precipitation amounts. A trend analysis of annual precipitation depths from 1948 through 2015 indicated a declining pattern in rainfall between 1948 through 1969 and a slightly inclining pattern from 1970 through 2015. As the latter trend is more relevant to present day, subsequent statistical analyses for the typical period were performed with precipitation records for the recent 46-year period (1970 through 2015).

Key criteria parameters for the typical year evaluation were identified based on the requirements of the presumption and demonstration approaches of the National CSO Control Policy and potential operational and maintenance considerations for control facilities. Each

parameter was given a weighting factor to describe the individual importance on the average design condition. The key criteria parameters evaluated were:

- Annual precipitation depth;
- Number of events with rainfall depth equal to or greater than 0.2 inch;
- Number of events with rainfall depth equal to or greater than 0.1 inch;
- The 5th largest storm volume;
- Rainfall volume for 85% captured;
- Number of back-to-back rainfall events;
- Maximum peak intensity of the 5th largest storm and less,
- Number of storm events with return frequency equal to or greater than 1-year;
- Average rainfall duration, and
- Average rainfall intensity.

Based on the statistical and ranking analysis of the 46-year time series, the NJ CSO Group selected the 2004 calendar year as the average annual hydrologic period for the CSO LTCP evaluations. Individual rainfall events within each year were disaggregated from the overall dataset using a 6-hour dry weather inter-event time interval and statistics for the key criteria parameters were calculated on an annual basis from these individual events. The 46 years were then ranked based on the lowest sum of the weighted deviation from the average over the entire period for each parameter. Years with an annual precipitation depth less than the period average were excluded from the final rankings to provide a more conservative selection.

The NJ CSO Group also conducted a continuous hydrologic and hydraulic model simulation for the period from 1996 to 2015 using a model that included 5 CSO communities in the PVSC service area. The model results indicate that the predicted overflow statistics for 2004 are slighter higher than the simulation period averages, being 1.5% greater than average for CSO volume and 6.7% greater than average for CSO event number. Overall, the 2004 precipitation record was selected as the typical hydrologic year based on the ranking analysis and modeling results. The 2004 calendar year contains a wide range of storms and antecedent conditions and has close to an average CSO volume and event number based on the hydrologic and hydraulic model results.

The 2004 precipitation record for the Newark Liberty International Airport NOAA gauge, as received from NJ CSO Group, was utilized for the typical year existing conditions characterization. Table 8-1 summarizes the ranking criteria parameter values for the 2004 calendar year and Table 8-2 indicates the top 20 rainfall events by depth in 2004. The total annual precipitation depth for 2004 was 48.37 inches. The largest 1-hour composited rainfall intensity of 1.33 inches per hour is associated with the storm starting on September 17, 2004, while the maximum peak intensity of the 5th largest and smaller storm is 0.99 inches per hour and the overall average intensity for the year was 0.084 inches per hour.

Table 8-1: Selected Typical Hydrologic Year 2004 Ranking Parameter Values

Ranking Criteria Parameter	Year 2004 Value
Annual Precipitation Depth (inches)	48.37 *
Number of Events ≥ 0.2 " Rainfall Depth	54
Number of Events ≥ 0.1 " Rainfall Depth	73
5th Largest Storm Volume (inches)	1.63
Rainfall Volume for 85% Capture (inches)	1.18
Number of Back-to-Back Rainfall Events	12

Ranking Criteria Parameter	Year 2004 Value
Max Peak Intensity of 5th Largest Storm and Less (inches per hour)	0.99
Number of storm events with return frequency equal to or greater than 1-year	3 total: (2) 1-year storms; (1) 2-year storm
Average Rainfall Duration (hours)	10.3
Average Rainfall Intensity (inches per hour)	0.084

8.2 Typical Year Existing Conditions Simulation Results

The CSO drainage basins within the City of Elizabeth are tributary to the Trenton Avenue Pump Station. Thereafter, it is pumped into the JMEUC incoming trunk sewer to the JMEUC wastewater treatment plant. The calibrated and validated Infoworks ICM model for the City of Elizabeth collection system was merged with the JMEUC ICM model for the 2004 typical year simulation, as that provides accurate tailwater conditions for the pump station force main.

The ICM model was set up to run in continuous simulation for the entire 2004 year, with tidal boundary conditions for the CSO outfalls and the JMEUC system as the downstream boundary condition for Trenton Avenue Pump Station. The 2004 precipitation dataset provided by NJ CSO Group was used in the analysis. The total CSO overflow events and volumes across all outfalls were calculated for the system characterization. Table 8-3 tabulates the typical year existing conditions simulation results by outfall location for the annual total number of overflow

events, overflow volume, and duration, and the peak flow occurrence. Figure 8-1 graphically indicates the monthly distribution of the system-wide number of overflow events and total overflow volumes, along with the monthly precipitation depths for the 2004 typical year. Appendix J contains tables characterizing the monthly CSO event frequencies, volumes, durations, and peak flows for each outfall and system-wide for the typical year existing conditions simulation model run.

The durations noted are the total cumulative time of CSO discharge for the indicated period and outfall location. The system-wide event counts, durations, and peak flows are the maximum values across all outfalls for the noted period.

Table 8-3: Annual Total CSO Frequency, Volume, and Duration by Outfall

Outfall No.	Outfall Name	Annual Total		Maximum	
		No. Overflow Events	Overflow Volume (Mgal)	Duration (hours)	Peak Flow (mgd)
001A	Airport South Area	35	75.78	246.26	75.09
002A	Dowd Avenue	35	30.86	221.01	62.30
003A	Westfield Avenue & Magie Avenue	42	59.43	270.67	191.43
005A	Westfield Avenue	53	85.14	540.38	62.15
008A	West Grand Street/Price Street	35	8.19	215.77	11.86
010A	Murray Street/Cherry Street	43	17.17	270.16	31.76
012A	Rahway Avenue	38	3.75	264.25	1.40
013A	Rahway Avenue/Burnet Street	40	16.56	298.93	22.95
014A	Broad Street Rahway Avenue	10	0.66	13.08	4.87
016A	Edgar Road/Pearl Street	46	15.83	334.85	28.05
021A	Spring Street/Third Avenue	9	0.57	20.04	5.45
022A	South Street	46	66.75	419.29	66.54
026A	John Street	56	51.77	564.55	56.24
027A	Summer Street/Arnett Street	36	54.49	306.54	57.69
028A	Summer Street/Arnett Street	30	12.49	162.22	41.90
029A	South Front Street	36	45.95	227.39	64.45
030A	Front Street/East Jersey Street	9	1.18	5.13	31.60
031A	Front Street/Livingston Street	31	12.28	196.97	35.34
032A	Front Street/Magnolia Avenue	25	6.94	82.09	43.19
034A	Atalanta Place	40	81.03	321.59	76.38

041A	Morris Avenue/Sayre Street	53	175.79	532.72	147.33
042A	Bridge Street/Elizabeth River	52	38.53	491.75	96.87
043A	Army Corps Flood Control Structure	2	0.05	0.47	5.98
System-wide Total		not appl.	1064.90	not appl.	not appl.
System-wide Maximum		56	175.79	564.55	191.43

Figure 8-1: System-wide Monthly CSO Overflow Event Frequencies and Volumes

The number of overflow events were counted based on a 24-hour time interval between events as described in the NJPDES CSO Permit, which states that multiple periods of overflow from one or more outfalls are considered one overflow event if the time between periods of overflow is less than 24 hours without a discharge from any outfall. The overflow occurrences for all outfall regulators were arranged chronologically and the discharge start and end times were compared. Any overflow that started within 24 hours of the end of the last discharge was considered the same overflow event. Any overflow that started 24 hours after the end of the prior discharge was considered the start of a new overflow event.

A tabulation of the overflow periods, durations, volumes, and peak flow rates on a CSO event basis per the typical year existing conditions simulation results is given in Table 8-4. The durations correspond to the total time period when any of the outfalls are discharging and the overflow volume is the sum of the calculated volumes from the outfall discharges system-wide for the event. The peak flow is the maximum calculated flow that occurred at any outfall during the event.

The maximum total number of CSO events that occurs throughout the system in the typical year is calculated to be 56 and corresponds to Outfall 026A, John Street. Outfall 005A, Westfield Avenue, and Outfall 041A, Morris Avenue/Sayre Street, share the next highest overflow frequency of 53 events per year, while Outfall 042A, Bridge Street, is the 4th most active with 52 events per year. After that, the CSO event frequency distribution then drops to 46 events per year. On the lower end, the smaller CSO basins associated with relief Outfall 021A, Spring Street/Third Avenue, and Outfall 030A, Front Street/East Jersey Street, are each predicted to have 9 overflow events per year, on average. With the typical year precipitation conditions, 2 overflow occurrences are predicted for the emergency relief Outfall 043A, Army Corps Flood Control Structure, which relieves the primary Outfall 035A, South Front Street/Third Avenue, during heavy storm and high tidal conditions.

Outfall 041A has the highest estimated total overflow volume at about 176 million gallons per year (Mgal/yr), while the second largest annual total overflow volume is substantially lower at approximately 85 Mgal/yr corresponding to Outfall 005A. Outfalls 026A, 005A, 041A have the 3 largest estimated total overflow durations per year and Outfall 003A, Westfield Avenue & Magie Avenue, along with Outfalls 041A and 042A have the 3 highest simulated peak CSO flow throughout the year.

The system-wide total overflow volume for each overflow event are plotted in descending order in Figure 8-2. The overflow volume associated with the 5th largest event is an important parameter in sizing CSO control alternatives as it represents the storage volume that may be needed such that no more than 4 overflow events per year occur on average, in accordance with one of the presumption approach conditions of the National CSO Control Policy. As shown in the figure, the 5th largest event corresponds to a total overflow volume of approximately 57 million gallons.

Table 8-4: Typical Year Event Summary Tabulation

Event No.	Event Start Time	Event End Time	Total Duration (hours)	Total Overflow Volume (Mgal)	Peak Flow (mgd)
1	1/4/2004 19:51	1/5/2004 15:16	19.43	7.03	10.81
2	1/15/2004 7:47	1/15/2004 11:48	4.02	0.12	1.71

DEFINITIONS

Eurofins OC, Inc. (EOC)

The following terms or abbreviations are used in this report:

MPN	Most probable number	PL	Customer-specific limit
CFU	Colony forming unit	DF	Dilution Factor (For Microbiology, DF = volume of sample tested)
POS	Positive / Present	QUAL	Qualifier (Q)
NEG	Negative / Absent	NTU	Nephelometric turbidity units
PRES	Presumptive	RL	Laboratory reporting limit or Limit of Quantitation (LOQ)
MF	Membrane Filtration	MCL	EPA recommended "Maximum Contaminant Level"
TNTC	Too numerous to count	MDL	Method Detection Limit
DRY	The result was reported on a dry weight basis.	ND	Analyte concentration not detected greater than the RL / MDL

TIC	Tentatively Identified Compounds (Library Search Compounds); concentrations are estimated values only.
ppm (mg/l)	Parts per million: equivalent to 1 milligram per kilogram (mg/Kg) for solids or one milligram per liter (mg/L) for aqueous samples.
ppb (ug/L)	Parts per billion: equivalent to 1 microgram per kilogram (ug/Kg) for solids or one microgram per liter (ug/L) for aqueous samples.
<	Less than: In conjunction with a numerical value, indicates a concentration less than RL / MDL.
>	Greater than: In conjunction with a numerical value, indicates a concentration greater than RL / MDL.

Data Qualifiers (EPA CLP Convention)

J	Estimated value \geq MDL but < RL.	E	Metals: Estimated value due to presence of interference
B	Analyte was detected in the method blank	E	Organics: Concentration exceeds calibration range.
U	Analyte not detected above RL or MDL, when MDL reported.	E	Microbiology: estimated CFU count
N	Presumptive evidence of compound in library search	M	Metals: Duplicate precision for an element outside control limit
P1 or P	Column precision criteria not met, report lower value	N	Metals: Spike recovery for an element outside control limits
P2	Column precision criteria not met, report higher value	C	Result confirmed by reanalysis
		Q	Defined in report or case narrative or data package
T	Temperature receipt exceedance, refer to Sample Comments/ Results Qualifiers section.	V	Analyte concentration >100% between columns; reporting limit elevated

Warranties, Terms, and Conditions

- Unless otherwise specified in the Parameter field, analyses (excluding "Field Parameters") were performed at the EQC Southampton facility (1205 Industrial Boulevard, Southampton, PA 18966). Pharmaceutical testing is performed the EQC facility in Horsham (702 Electronic Drive, Horsham, PA 19044).
- The test results meet all TNI or other applicable regulatory agency requirements, including holding times and preservation, unless otherwise indicated.
- The report shall not be reproduced, except in full, without the written consent of the laboratory.
- All samples are collected as "grab" samples unless otherwise identified.
- The reported results relate only to the sample as tested. EQC is not responsible for sample integrity unless sampling has been performed by a member of our staff.
- EQC is not responsible for sampling and/or testing omissions. Note that regulatory authorities may assess substantial fines for testing omissions. Please track your sample collection schedules and results on a regular basis (e.g. weekly, monthly, or quarterly) to ensure compliance. EQC's internet program "LIVE ACCESS" will provide you with real-time access to collection dates and testing results. Please contact Customer Service for further information.
- The following personnel or their deputies have approved the results of the tests performed by EQC: Nicki Smith (Environmental Chemistry), Amanda Berd (Pharmaceutical), Sue Abbott (EQC Delaware).

DEFINITIONS

Eurofins OC, Inc. (EOC)

The following terms or abbreviations are used in this report:

MPN	Most probable number	PL	Customer-specific limit
CFU	Colony forming unit	DF	Dilution Factor (For Microbiology, DF = volume of sample tested)
POS	Positive / Present	QUAL	Qualifier (Q)
NEG	Negative / Absent	NTU	Nephelometric turbidity units
PRES	Presumptive	RL	Laboratory reporting limit or Limit of Quantitation (LOQ)
MF	Membrane Filtration	MCL	EPA recommended "Maximum Contaminant Level"
TNTC	Too numerous to count	MDL	Method Detection Limit
DRY	The result was reported on a dry weight basis.	ND	Analyte concentration not detected greater than the RL / MDL

TIC	Tentatively Identified Compounds (Library Search Compounds); concentrations are estimated values only.
ppm (mg/l)	Parts per million: equivalent to 1 milligram per kilogram (mg/Kg) for solids or one milligram per liter (mg/L) for aqueous samples.
ppb (ug/L)	Parts per billion: equivalent to 1 microgram per kilogram (ug/Kg) for solids or one microgram per liter (ug/L) for aqueous samples.
<	Less than: In conjunction with a numerical value, indicates a concentration less than RL / MDL.
>	Greater than: In conjunction with a numerical value, indicates a concentration greater than RL / MDL.

Data Qualifiers (EPA CLP Convention)

J	Estimated value \geq MDL but < RL.	E	Metals: Estimated value due to presence of interference
B	Analyte was detected in the method blank	E	Organics: Concentration exceeds calibration range.
U	Analyte not detected above RL or MDL, when MDL reported.	E	Microbiology: estimated CFU count
N	Presumptive evidence of compound in library search	M	Metals: Duplicate precision for an element outside control limit
P1 or P	Column precision criteria not met, report lower value	N	Metals: Spike recovery for an element outside control limits
P2	Column precision criteria not met, report higher value	C	Result confirmed by reanalysis
		Q	Defined in report or case narrative or data package
T	Temperature receipt exceedance, refer to Sample Comments/ Results Qualifiers section.	V	Analyte concentration >100% between columns; reporting limit elevated

Warranties, Terms, and Conditions

- Unless otherwise specified in the Parameter field, analyses (excluding "Field Parameters") were performed at the EQC Southampton facility (1205 Industrial Boulevard, Southampton, PA 18966). Pharmaceutical testing is performed the EQC facility in Horsham (702 Electronic Drive, Horsham, PA 19044).
- The test results meet all TNI or other applicable regulatory agency requirements, including holding times and preservation, unless otherwise indicated.
- The report shall not be reproduced, except in full, without the written consent of the laboratory.
- All samples are collected as "grab" samples unless otherwise identified.
- The reported results relate only to the sample as tested. EQC is not responsible for sample integrity unless sampling has been performed by a member of our staff.
- EQC is not responsible for sampling and/or testing omissions. Note that regulatory authorities may assess substantial fines for testing omissions. Please track your sample collection schedules and results on a regular basis (e.g. weekly, monthly, or quarterly) to ensure compliance. EQC's internet program "LIVE ACCESS" will provide you with real-time access to collection dates and testing results. Please contact Customer Service for further information.
- The following personnel or their deputies have approved the results of the tests performed by EQC: Nicki Smith (Environmental Chemistry), Amanda Berd (Pharmaceutical), Sue Abbott (EQC Delaware).

DEFINITIONS

Eurofins OC, Inc. (EOC)

The following terms or abbreviations are used in this report:

MPN	Most probable number	PL	Customer-specific limit
CFU	Colony forming unit	DF	Dilution Factor (For Microbiology, DF = volume of sample tested)
POS	Positive / Present	QUAL	Qualifier (Q)
NEG	Negative / Absent	NTU	Nephelometric turbidity units
PRES	Presumptive	RL	Laboratory reporting limit or Limit of Quantitation (LOQ)
MF	Membrane Filtration	MCL	EPA recommended "Maximum Contaminant Level"
TNTC	Too numerous to count	MDL	Method Detection Limit
DRY	The result was reported on a dry weight basis.	ND	Analyte concentration not detected greater than the RL / MDL

TIC	Tentatively Identified Compounds (Library Search Compounds); concentrations are estimated values only.
ppm (mg/l)	Parts per million: equivalent to 1 milligram per kilogram (mg/Kg) for solids or one milligram per liter (mg/L) for aqueous samples.
ppb (ug/L)	Parts per billion: equivalent to 1 microgram per kilogram (ug/Kg) for solids or one microgram per liter (ug/L) for aqueous samples.
<	Less than: In conjunction with a numerical value, indicates a concentration less than RL / MDL.
>	Greater than: In conjunction with a numerical value, indicates a concentration greater than RL / MDL.

Data Qualifiers (EPA CLP Convention)

J	Estimated value \geq MDL but < RL.	E	Metals: Estimated value due to presence of interference
B	Analyte was detected in the method blank	E	Organics: Concentration exceeds calibration range.
U	Analyte not detected above RL or MDL, when MDL reported.	E	Microbiology: estimated CFU count
N	Presumptive evidence of compound in library search	M	Metals: Duplicate precision for an element outside control limit
P1 or P	Column precision criteria not met, report lower value	N	Metals: Spike recovery for an element outside control limits
P2	Column precision criteria not met, report higher value	C	Result confirmed by reanalysis
		Q	Defined in report or case narrative or data package
T	Temperature receipt exceedance, refer to Sample Comments/ Results Qualifiers section.	V	Analyte concentration >100% between columns; reporting limit elevated

Warranties, Terms, and Conditions

- Unless otherwise specified in the Parameter field, analyses (excluding "Field Parameters") were performed at the EQC Southampton facility (1205 Industrial Boulevard, Southampton, PA 18966). Pharmaceutical testing is performed the EQC facility in Horsham (702 Electronic Drive, Horsham, PA 19044).
- The test results meet all TNI or other applicable regulatory agency requirements, including holding times and preservation, unless otherwise indicated.
- The report shall not be reproduced, except in full, without the written consent of the laboratory.
- All samples are collected as "grab" samples unless otherwise identified.
- The reported results relate only to the sample as tested. EQC is not responsible for sample integrity unless sampling has been performed by a member of our staff.
- EQC is not responsible for sampling and/or testing omissions. Note that regulatory authorities may assess substantial fines for testing omissions. Please track your sample collection schedules and results on a regular basis (e.g. weekly, monthly, or quarterly) to ensure compliance. EQC's internet program "LIVE ACCESS" will provide you with real-time access to collection dates and testing results. Please contact Customer Service for further information.
- The following personnel or their deputies have approved the results of the tests performed by EQC: Nicki Smith (Environmental Chemistry), Amanda Berd (Pharmaceutical), Sue Abbott (EQC Delaware).

DEFINITIONS

Eurofins OC, Inc. (EOC)

The following terms or abbreviations are used in this report:

MPN	Most probable number	PL	Customer-specific limit
CFU	Colony forming unit	DF	Dilution Factor (For Microbiology, DF = volume of sample tested)
POS	Positive / Present	QUAL	Qualifier (Q)
NEG	Negative / Absent	NTU	Nephelometric turbidity units
PRES	Presumptive	RL	Laboratory reporting limit or Limit of Quantitation (LOQ)
MF	Membrane Filtration	MCL	EPA recommended "Maximum Contaminant Level"
TNTC	Too numerous to count	MDL	Method Detection Limit
DRY	The result was reported on a dry weight basis.	ND	Analyte concentration not detected greater than the RL / MDL

TIC	Tentatively Identified Compounds (Library Search Compounds); concentrations are estimated values only.
ppm (mg/l)	Parts per million: equivalent to 1 milligram per kilogram (mg/Kg) for solids or one milligram per liter (mg/L) for aqueous samples.
ppb (ug/L)	Parts per billion: equivalent to 1 microgram per kilogram (ug/Kg) for solids or one microgram per liter (ug/L) for aqueous samples.
<	Less than: In conjunction with a numerical value, indicates a concentration less than RL / MDL.
>	Greater than: In conjunction with a numerical value, indicates a concentration greater than RL / MDL.

Data Qualifiers (EPA CLP Convention)

J	Estimated value \geq MDL but < RL.	E	Metals: Estimated value due to presence of interference
B	Analyte was detected in the method blank	E	Organics: Concentration exceeds calibration range.
U	Analyte not detected above RL or MDL, when MDL reported.	E	Microbiology: estimated CFU count
N	Presumptive evidence of compound in library search	M	Metals: Duplicate precision for an element outside control limit
P1 or P	Column precision criteria not met, report lower value	N	Metals: Spike recovery for an element outside control limits
P2	Column precision criteria not met, report higher value	C	Result confirmed by reanalysis
		Q	Defined in report or case narrative or data package
T	Temperature receipt exceedance, refer to Sample Comments/ Results Qualifiers section.	V	Analyte concentration >100% between columns; reporting limit elevated

Warranties, Terms, and Conditions

- Unless otherwise specified in the Parameter field, analyses (excluding "Field Parameters") were performed at the EQC Southampton facility (1205 Industrial Boulevard, Southampton, PA 18966). Pharmaceutical testing is performed the EQC facility in Horsham (702 Electronic Drive, Horsham, PA 19044).
- The test results meet all TNI or other applicable regulatory agency requirements, including holding times and preservation, unless otherwise indicated.
- The report shall not be reproduced, except in full, without the written consent of the laboratory.
- All samples are collected as "grab" samples unless otherwise identified.
- The reported results relate only to the sample as tested. EQC is not responsible for sample integrity unless sampling has been performed by a member of our staff.
- EQC is not responsible for sampling and/or testing omissions. Note that regulatory authorities may assess substantial fines for testing omissions. Please track your sample collection schedules and results on a regular basis (e.g. weekly, monthly, or quarterly) to ensure compliance. EQC's internet program "LIVE ACCESS" will provide you with real-time access to collection dates and testing results. Please contact Customer Service for further information.
- The following personnel or their deputies have approved the results of the tests performed by EQC: Nicki Smith (Environmental Chemistry), Amanda Berd (Pharmaceutical), Sue Abbott (EQC Delaware).

The following terms or abbreviations are used in this report:

MPN	Most probable number	PL	Customer-specific limit
CFU	Colony forming unit	DF	Dilution Factor (For Microbiology, DF = volume of sample tested)
POS	Positive / Present	QUAL	Qualifier (Q)
NEG	Negative / Absent	NTU	Nephelometric turbidity units
PRES	Presumptive	RL	Laboratory reporting limit or Limit of Quantitation (LOQ)
MF	Membrane Filtration	MCL	EPA recommended "Maximum Contaminant Level"
TNTC	Too numerous to count	MDL	Method Detection Limit
DRY	The result was reported on a dry weight basis.	ND	Analyte concentration not detected greater than the RL / MDL

TIC	Tentatively Identified Compounds (Library Search Compounds); concentrations are estimated values only.
ppm (mg/l)	Parts per million: equivalent to 1 milligram per kilogram (mg/Kg) for solids or one milligram per liter (mg/L) for aqueous samples.
ppb (ug/L)	Parts per billion: equivalent to 1 microgram per kilogram (ug/Kg) for solids or one microgram per liter (ug/L) for aqueous samples.
<	Less than: In conjunction with a numerical value, indicates a concentration less than RL / MDL.
>	Greater than: In conjunction with a numerical value, indicates a concentration greater than RL / MDL.

Data Qualifiers (EPA CLP Convention)

J	Estimated value \geq MDL but < RL.	E	Metals: Estimated value due to presence of interference
B	Analyte was detected in the method blank	E	Organics: Concentration exceeds calibration range.
U	Analyte not detected above RL or MDL, when MDL reported.	E	Microbiology: estimated CFU count
N	Presumptive evidence of compound in library search	M	Metals: Duplicate precision for an element outside control limit
P1 or P	Column precision criteria not met, report lower value	N	Metals: Spike recovery for an element outside control limits
P2	Column precision criteria not met, report higher value	C	Result confirmed by reanalysis
		Q	Defined in report or case narrative or data package
T	Temperature receipt exceedance, refer to Sample Comments/ Results Qualifiers section.	V	Analyte concentration >100% between columns; reporting limit elevated

Warranties, Terms, and Conditions

- Unless otherwise specified in the Parameter field, analyses (excluding "Field Parameters") were performed at the EQC Southampton facility (1205 Industrial Boulevard, Southampton, PA 18966). Pharmaceutical testing is performed the EQC facility in Horsham (702 Electronic Drive, Horsham, PA 19044).
- The test results meet all TNI or other applicable regulatory agency requirements, including holding times and preservation, unless otherwise indicated.
- The report shall not be reproduced, except in full, without the written consent of the laboratory.
- All samples are collected as "grab" samples unless otherwise identified.
- The reported results relate only to the sample as tested. EQC is not responsible for sample integrity unless sampling has been performed by a member of our staff.
- EQC is not responsible for sampling and/or testing omissions. Note that regulatory authorities may assess substantial fines for testing omissions. Please track your sample collection schedules and results on a regular basis (e.g. weekly, monthly, or quarterly) to ensure compliance. EQC's internet program "LIVE ACCESS" will provide you with real-time access to collection dates and testing results. Please contact Customer Service for further information.
- The following personnel or their deputies have approved the results of the tests performed by EQC: Nicki Smith (Environmental Chemistry), Amanda Berd (Pharmaceutical), Sue Abbott (EQC Delaware).

DEFINITIONS

Eurofins OC, Inc. (EOC)

The following terms or abbreviations are used in this report:

MPN	Most probable number	PL	Customer-specific limit
CFU	Colony forming unit	DF	Dilution Factor (For Microbiology, DF = volume of sample tested)
POS	Positive / Present	QUAL	Qualifier (Q)
NEG	Negative / Absent	NTU	Nephelometric turbidity units
PRES	Presumptive	RL	Laboratory reporting limit or Limit of Quantitation (LOQ)
MF	Membrane Filtration	MCL	EPA recommended "Maximum Contaminant Level"
TNTC	Too numerous to count	MDL	Method Detection Limit
DRY	The result was reported on a dry weight basis.	ND	Analyte concentration not detected greater than the RL / MDL

TIC Tentatively Identified Compounds (Library Search Compounds); concentrations are estimated values only.

ppm (mg/l) Parts per million: equivalent to 1 milligram per kilogram (mg/Kg) for solids or one milligram per liter (mg/L) for aqueous samples.

ppb (ug/L) Parts per billion: equivalent to 1 microgram per kilogram (ug/Kg) for solids or one microgram per liter (ug/L) for aqueous samples.

< Less than: In conjunction with a numerical value, indicates a concentration less than RL / MDL.

> Greater than: In conjunction with a numerical value, indicates a concentration greater than RL / MDL.

Data Qualifiers (EPA CLP Convention)

J	Estimated value \geq MDL but < RL.	E	Metals: Estimated value due to presence of interference
B	Analyte was detected in the method blank	E	Organics: Concentration exceeds calibration range.
U	Analyte not detected above RL or MDL, when MDL reported.	E	Microbiology: estimated CFU count
N	Presumptive evidence of compound in library search	M	Metals: Duplicate precision for an element outside control limit
P1 or P	Column precision criteria not met, report lower value	N	Metals: Spike recovery for an element outside control limits
P2	Column precision criteria not met, report higher value	C	Result confirmed by reanalysis
W	Dissolved Oxygen uptake in the unseeded blank is greater than 0.20 mg/L.	Q	Defined in report or case narrative or data package
T	Temperature receipt exceedance, refer to Sample Comments/ Results Qualifiers section.	V	Analyte concentration >100% between columns; reporting limit elevated

Warranties, Terms, and Conditions

- Unless otherwise specified in the Parameter field, analyses (excluding "Field Parameters") were performed at the EQC Southampton facility (1205 Industrial Boulevard, Southampton, PA 18966). Pharmaceutical testing is performed the EQC facility in Horsham (702 Electronic Drive, Horsham, PA 19044).
- The test results meet all TNI or other applicable regulatory agency requirements, including holding times and preservation, unless otherwise indicated.
- The report shall not be reproduced, except in full, without the written consent of the laboratory.
- All samples are collected as "grab" samples unless otherwise identified.
- The reported results relate only to the sample as tested. EQC is not responsible for sample integrity unless sampling has been performed by a member of our staff.
- EQC is not responsible for sampling and/or testing omissions. Note that regulatory authorities may assess substantial fines for testing omissions. Please track your sample collection schedules and results on a regular basis (e.g. weekly, monthly, or quarterly) to ensure compliance. EQC's internet program "LIVE ACCESS" will provide you with real-time access to collection dates and testing results. Please contact Customer Service for further information.
- The following personnel or their deputies have approved the results of the tests performed by EQC: Nicki Smith (Environmental Chemistry), Amanda Berd (Pharmaceutical), Sue Abbott (EQC Delaware).

DEFINITIONS

Eurofins OC, Inc. (EOC)

The following terms or abbreviations are used in this report:

MPN	Most probable number	PL	Customer-specific limit
CFU	Colony forming unit	DF	Dilution Factor (For Microbiology, DF = volume of sample tested)
POS	Positive / Present	QUAL	Qualifier (Q)
NEG	Negative / Absent	NTU	Nephelometric turbidity units
PRES	Presumptive	RL	Laboratory reporting limit or Limit of Quantitation (LOQ)
MF	Membrane Filtration	MCL	EPA recommended "Maximum Contaminant Level"
TNTC	Too numerous to count	MDL	Method Detection Limit
DRY	The result was reported on a dry weight basis.	ND	Analyte concentration not detected greater than the RL / MDL
TON	Threshold Odor Number		

ppm (mg/l) Parts per million: equivalent to 1 milligram per kilogram (mg/Kg) for solids or one milligram per liter (mg/L) for aqueous samples.

ppb (ug/L) Parts per billion: equivalent to 1 microgram per kilogram (ug/Kg) for solids or one microgram per liter (ug/L) for aqueous samples.

< Less than: In conjunction with a numerical value, indicates a concentration less than RL / MDL.

> Greater than: In conjunction with a numerical value, indicates a concentration greater than RL / MDL.

Data Qualifiers

J	Estimated value \geq MDL but < RL.
T	Temperature receipt exceedance, refer to Sample Comments/ Results Qualifiers section.
E	Microbiology: estimated CFU count
Q	Qualifier: defined in Sample Comment section

Warranties, Terms, and Conditions

- Unless otherwise specified in the Parameter field, analyses (excluding "Field Parameters") were performed at the EQCI Southampton facility (1205 Industrial Boulevard, Southampton, PA 18966). Pharmaceutical testing is performed the EQCI facility in Horsham (702 Electronic Drive, Horsham, PA 19044).
- The test results meet all TNI or other applicable regulatory agency requirements, including holding times and preservation, unless otherwise indicated.
- The report shall not be reproduced, except in full, without the written consent of the laboratory.
- All samples are collected as "grab" samples unless otherwise identified.
- The reported results relate only to the sample as tested. EQCI is not responsible for sample integrity unless sampling has been performed by a member of our staff.
- EQCI is not responsible for sampling and/or testing omissions. Note that regulatory authorities may assess substantial fines for testing omissions. Please track your sample collection schedules and results on a regular basis (e.g. weekly, monthly, or quarterly) to ensure compliance. EQCI's internet program "LIVE ACCESS" will provide you with real-time access to collection dates and testing results. Please contact Customer Service for further information.
- The following personnel or their deputies have approved the results of the tests performed by EQCI: Nicki Smith (Environmental Chemistry), Amanda Berd (Pharmaceutical), Sue Abbott (EQCI Delaware).

RL*
100000

Analytical Method: SM 9222D
Dilution: .0001
Units: cfu/100ml

Run Date: 04/26/17 12:20AM
Analyst: DYS
Instrument:

Workgroup:
File ID: WM_LOGBOOK_SAT 75946 L6754411-23
Basis:

Parameter
Fecal Coliform, MF

CAS
N/A

Result
36000000

MDL
N/A

RL*
1000000

*=This limit was used in the evaluation of the final result.

PIN: 27634

Serial Number: 6275459

DEFINITIONS

Eurofins OC, Inc. (EOC)

The following terms or abbreviations are used in this report:

MPN	Most probable number	PL	Customer-specific limit
CFU	Colony forming unit	DF	Dilution Factor (For Microbiology, DF = volume of sample tested)
POS	Positive / Present	QUAL	Qualifier (Q)
NEG	Negative / Absent	NTU	Nephelometric turbidity units
PRES	Presumptive	RL	Laboratory reporting limit or Limit of Quantitation (LOQ)
MF	Membrane Filtration	MCL	EPA recommended "Maximum Contaminant Level"
TNTC	Too numerous to count	MDL	Method Detection Limit
DRY	The result was reported on a dry weight basis.	ND	Analyte concentration not detected greater than the RL / MDL
TON	Threshold Odor Number		

ppm (mg/l) Parts per million: equivalent to 1 milligram per kilogram (mg/Kg) for solids or one milligram per liter (mg/L) for aqueous samples.

ppb (ug/L) Parts per billion: equivalent to 1 microgram per kilogram (ug/Kg) for solids or one microgram per liter (ug/L) for aqueous samples.

< Less than: In conjunction with a numerical value, indicates a concentration less than RL / MDL.

> Greater than: In conjunction with a numerical value, indicates a concentration greater than RL / MDL.

Data Qualifiers

J	Estimated value \geq MDL but < RL.
T	Temperature receipt exceedance, refer to Sample Comments/ Results Qualifiers section.
E	Microbiology: estimated CFU count
Q	Qualifier: defined in Sample Comment section

Warranties, Terms, and Conditions

- Unless otherwise specified in the Parameter field, analyses (excluding "Field Parameters") were performed at the EQCI Southampton facility (1205 Industrial Boulevard, Southampton, PA 18966). Pharmaceutical testing is performed the EQCI facility in Horsham (702 Electronic Drive, Horsham, PA 19044).
- The test results meet all TNI or other applicable regulatory agency requirements, including holding times and preservation, unless otherwise indicated.
- The report shall not be reproduced, except in full, without the written consent of the laboratory.
- All samples are collected as "grab" samples unless otherwise identified.
- The reported results relate only to the sample as tested. EQCI is not responsible for sample integrity unless sampling has been performed by a member of our staff.
- EQCI is not responsible for sampling and/or testing omissions. Note that regulatory authorities may assess substantial fines for testing omissions. Please track your sample collection schedules and results on a regular basis (e.g. weekly, monthly, or quarterly) to ensure compliance. EQCI's internet program "LIVE ACCESS" will provide you with real-time access to collection dates and testing results. Please contact Customer Service for further information.
- The following personnel or their deputies have approved the results of the tests performed by EQCI: Nicki Smith (Environmental Chemistry), Amanda Berd (Pharmaceutical), Sue Abbott (EQCI Delaware).

DEFINITIONS

Eurofins OC, Inc. (EOC)

The following terms or abbreviations are used in this report:

MPN	Most probable number	PL	Customer-specific limit
CFU	Colony forming unit	DF	Dilution Factor (For Microbiology, DF = volume of sample tested)
POS	Positive / Present	QUAL	Qualifier (Q)
NEG	Negative / Absent	NTU	Nephelometric turbidity units
PRES	Presumptive	RL	Laboratory reporting limit or Limit of Quantitation (LOQ)
MF	Membrane Filtration	MCL	EPA recommended "Maximum Contaminant Level"
TNTC	Too numerous to count	MDL	Method Detection Limit
DRY	The result was reported on a dry weight basis.	ND	Analyte concentration not detected greater than the RL / MDL
TON	Threshold Odor Number		

ppm (mg/l) Parts per million: equivalent to 1 milligram per kilogram (mg/Kg) for solids or one milligram per liter (mg/L) for aqueous samples.

ppb (ug/L) Parts per billion: equivalent to 1 microgram per kilogram (ug/Kg) for solids or one microgram per liter (ug/L) for aqueous samples.

< Less than: In conjunction with a numerical value, indicates a concentration less than RL / MDL.

> Greater than: In conjunction with a numerical value, indicates a concentration greater than RL / MDL.

Data Qualifiers

J	Estimated value \geq MDL but < RL.
T	Temperature receipt exceedance, refer to Sample Comments/ Results Qualifiers section.
E	Microbiology: estimated CFU count
Q	Qualifier: defined in Sample Comment section

Warranties, Terms, and Conditions

- Unless otherwise specified in the Parameter field, analyses (excluding "Field Parameters") were performed at the EQCI Southampton facility (1205 Industrial Boulevard, Southampton, PA 18966). Pharmaceutical testing is performed the EQCI facility in Horsham (702 Electronic Drive, Horsham, PA 19044).
- The test results meet all TNI or other applicable regulatory agency requirements, including holding times and preservation, unless otherwise indicated.
- The report shall not be reproduced, except in full, without the written consent of the laboratory.
- All samples are collected as "grab" samples unless otherwise identified.
- The reported results relate only to the sample as tested. EQCI is not responsible for sample integrity unless sampling has been performed by a member of our staff.
- EQCI is not responsible for sampling and/or testing omissions. Note that regulatory authorities may assess substantial fines for testing omissions. Please track your sample collection schedules and results on a regular basis (e.g. weekly, monthly, or quarterly) to ensure compliance. EQCI's internet program "LIVE ACCESS" will provide you with real-time access to collection dates and testing results. Please contact Customer Service for further information.
- The following personnel or their deputies have approved the results of the tests performed by EQCI: Nicki Smith (Environmental Chemistry), Amanda Berd (Pharmaceutical), Sue Abbott (EQCI Delaware).

DEFINITIONS

Eurofins OC, Inc. (EOC)

The following terms or abbreviations are used in this report:

MPN	Most probable number	PL	Customer-specific limit
CFU	Colony forming unit	DF	Dilution Factor (For Microbiology, DF = volume of sample tested)
POS	Positive / Present	QUAL	Qualifier (Q)
NEG	Negative / Absent	NTU	Nephelometric turbidity units
PRES	Presumptive	RL	Laboratory reporting limit or Limit of Quantitation (LOQ)
MF	Membrane Filtration	MCL	EPA recommended "Maximum Contaminant Level"
TNTC	Too numerous to count	MDL	Method Detection Limit
DRY	The result was reported on a dry weight basis.	ND	Analyte concentration not detected greater than the RL / MDL
TON	Threshold Odor Number		

ppm (mg/l) Parts per million: equivalent to 1 milligram per kilogram (mg/Kg) for solids or one milligram per liter (mg/L) for aqueous samples.

ppb (ug/L) Parts per billion: equivalent to 1 microgram per kilogram (ug/Kg) for solids or one microgram per liter (ug/L) for aqueous samples.

< Less than: In conjunction with a numerical value, indicates a concentration less than RL / MDL.

> Greater than: In conjunction with a numerical value, indicates a concentration greater than RL / MDL.

Data Qualifiers

J	Estimated value \geq MDL but < RL.
T	Temperature receipt exceedance, refer to Sample Comments/ Results Qualifiers section.
E	Microbiology: estimated CFU count
Q	Qualifier: defined in Sample Comment section

Warranties, Terms, and Conditions

- Unless otherwise specified in the Parameter field, analyses (excluding "Field Parameters") were performed at the EQCI Southampton facility (1205 Industrial Boulevard, Southampton, PA 18966). Pharmaceutical testing is performed the EQCI facility in Horsham (702 Electronic Drive, Horsham, PA 19044).
- The test results meet all TNI or other applicable regulatory agency requirements, including holding times and preservation, unless otherwise indicated.
- The report shall not be reproduced, except in full, without the written consent of the laboratory.
- All samples are collected as "grab" samples unless otherwise identified.
- The reported results relate only to the sample as tested. EQCI is not responsible for sample integrity unless sampling has been performed by a member of our staff.
- EQCI is not responsible for sampling and/or testing omissions. Note that regulatory authorities may assess substantial fines for testing omissions. Please track your sample collection schedules and results on a regular basis (e.g. weekly, monthly, or quarterly) to ensure compliance. EQCI's internet program "LIVE ACCESS" will provide you with real-time access to collection dates and testing results. Please contact Customer Service for further information.
- The following personnel or their deputies have approved the results of the tests performed by EQCI: Nicki Smith (Environmental Chemistry), Amanda Berd (Pharmaceutical), Sue Abbott (EQCI Delaware).

DEFINITIONS

Eurofins OC, Inc. (EOC)

The following terms or abbreviations are used in this report:

MPN	Most probable number	DF	Dilution Factor (For Microbiology, DF = volume of sample tested)
CFU	Colony forming unit	QUAL	Qualifier (Q)
POS	Positive / Present	NTU	Nephelometric turbidity units
NEG	Negative / Absent	RL	Laboratory reporting limit or Limit of Quantitation (LOQ)
PRES	Presumptive	MCL	EPA recommended "Maximum Contaminant Level"
MF	Membrane Filtration	MDL	Method Detection Limit
TNTC	Too numerous to count	ND	Analyte concentration not detected greater than the RL / MDL
DRY	The result was reported on a dry weight basis.	ND	For the odor test: No Odor Observed
TON	Threshold Odor Number		

ppm (mg/l) Parts per million: equivalent to 1 milligram per kilogram (mg/Kg) for solids or one milligram per liter (mg/L) for aqueous samples.

ppb (ug/L) Parts per billion: equivalent to 1 microgram per kilogram (ug/Kg) for solids or one microgram per liter (ug/L) for aqueous samples.

< Less than: In conjunction with a numerical value, indicates a concentration less than RL / MDL.

> Greater than: In conjunction with a numerical value, indicates a concentration greater than RL / MDL.

Data Qualifiers

J	Estimated value \geq MDL but < RL.
T	Temperature receipt exceedance, refer to Sample Comments/ Results Qualifiers section.
E	Microbiology: estimated CFU count
Q	Qualifier: defined in Sample Comment section on report

Warranties, Terms, and Conditions

- Analyses for Odor and Odor Threshold are performed at the EQCI Southampton facility (1205 Industrial Boulevard, Southampton, PA 18966). Unless otherwise specified in the Parameter field, analyses (excluding "Field Parameters") for environmental microbiology, environmental chemistry, and pharmaceutical microbiology are performed at the EQCI Horsham facility (702 Electronic Dr. Horsham, PA 19044).
- The test results meet all TNI or other applicable regulatory agency requirements, including holding times and preservation, unless otherwise indicated.
- The report shall not be reproduced, except in full, without the written consent of the laboratory.
- All samples are collected as "grab" samples unless otherwise identified.
- The reported results relate only to the sample as tested. EQCI is not responsible for sample integrity unless sampling has been performed by a member of our staff.
- EQCI is not responsible for sampling and/or testing omissions. Note that regulatory authorities may assess substantial fines for testing omissions. Please track your sample collection schedules and results on a regular basis (e.g. weekly, monthly, or quarterly) to ensure compliance. EQCI's internet program "LIVE ACCESS" will provide you with real-time access to collection dates and testing results. Please contact Customer Service for further information.
- The following personnel or their deputies have approved the results of the tests performed by EQCI: Nicki Smith (Environmental Chemistry), Amanda Berd (Pharmaceutical), Sue Abbott (EQCI Delaware), and Bhavita Shah (EQCI Horsham, Microbiology).

F. Rainfall Hyetographs

This page left intentionally blank for pagination.

Hourly Hyetograph for Storm on September 9, 2015

Total Rainfall = 0.03 inches

Hourly Hyetograph for Storm on September 10, 2015

Total Rainfall = 1.17 inches

Hourly Hyetograph for Storm on September 29 - 30, 2015
Total Rainfall = 1.41 inches

Hourly Hyetograph for Storm on October 2 - 3, 2015

Total Rainfall = 1.91 inches

Hourly Hyetograph for Storm on October 9, 2015

Total Rainfall = 0.38 inches

Hourly Hyetograph for Storm on October 28 - 29, 2015
Total Rainfall = 1.79 inches

Hourly Hyetograph for Storm on November 10 - 11, 2015

Total Rainfall = 0.62 inches

Hourly Hyetograph for Storm on November 19, 2015

Total Rainfall = 1.16 inches

Hourly Hyetograph for Storm on December 1 - 2, 2015
Total Rainfall = 0.67 inches

Hourly Hyetograph for Storm on December 17, 2015

Total Rainfall = 1.26 inches

G. Wet Weather Flow Calibration Results

Re: Review of "Typical Hydrologic Year Report"

Dear Ms. McKenna:

This letter is written to acknowledge receipt of and provide a determination on your submission dated May 2, 2018 entitled "Typical Hydrologic Year Report". This submission was prepared by PVSC on behalf of the New Jersey Combined Sewer Overflow (NJ CSO) Group permittees and includes certifications from the 21 permittees as per Part IV.D.1.b. As you know, the typical year (also known as average design conditions) is a major element for the Characterization Monitoring and Modeling of the Combined Sewer System as required by Part IV.G.1 of all New Jersey Pollutant Discharge Elimination System (NJPDDES) CSO permits. This report describes the methodology that was utilized for the Typical Hydrologic Year section, the analysis that was completed, and the recommended Typical Hydrologic Year to be used in the development of a CSO Long Term Control Plan (LTCP).

The Department has reviewed your submission and has determined that all questions and comments have been addressed to the Department's satisfaction.

Thank you for your continued cooperation. Feel free to contact me at (609) 292-4860 or at susan.rosenwinkel@dep.nj.gov if you have any questions regarding this letter.

Sincerely,

Susan Rosenwinkel
Acting Bureau Chief
Bureau of Surface Water Permitting

SECTION A - PROJECT MANAGEMENT

A.0 SUMMARY OF CHANGES

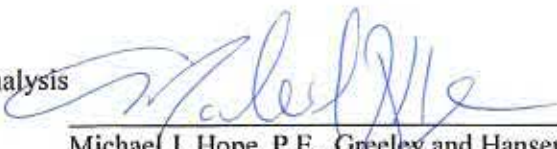

This Report is for the Typical Hydrologic Year to be utilized by the NJ CSO Group. This Report describes the methodology that was utilized for the Typical Hydrologic Year selection, the analysis that was completed, and the recommended Typical Hydrologic Year to be used in the development of a CSO Long Term Control Plan (LTCP). In future versions, this section will include summaries of changes and when they were incorporated as appropriate:

Section 1 Introduction

1.1 Typical Hydrologic Year Report Objectives for CSO LTCP Development

Precipitation generates urban storm water, combined sewer overflows (CSOs), and increased wet weather flows to the wastewater treatment plant. These will contribute bacteria and pollutants to the New York-New Jersey Harbor and its surrounding major tributaries. The effect of these contributors on the receiving streams mainly depends on the magnitude and duration of rainfall events and on the prevailing ambient river conditions controlling dilution and transport of the pollutants. This variability and complexity poses a significant challenge for assessing the performance of wet weather and CSO control alternatives.

In accordance with the USEPA CSO Control Policy (CSO Policy), dated April 19, 1994, the CSO control alternatives should be assessed on a “system-wide, annual average basis”. This is accomplished by continuous simulation using a typical hydrologic period for the combined sewer system (CSS) and receiving water quality modeling applications. The CSO Policy supports continuous simulation modeling, i.e., using long-term precipitation records rather than records for individual storms. Long-term continuous precipitation records enable simulations to be based on a sequence of storms so that the additive effect of storms occurring close together can be examined. They also enable storms with a range of characteristics to be included.

The representative year is intended to contain the closest to average year for the years with available data. Average year conditions are defined as the arithmetic average of the predictions for the selected period.

1.2 Principal Data Users

The principal users of the typical year selection will be PVSC, hydraulically connected PVSC member municipalities, the LTCP engineering consultants supporting PVSC, and other CSO municipalities who elect to utilize the typical year. PVSC is sharing the data generated for the selection of the typical year with the cooperating members of the NJ CSO Group and, therefore, the NJ CSO Group members may use the data to satisfy certain NJPDES permit requirements related to the requirements of their NJPDES Permits. **Table 1-1** defines the list of primary data users.

Secondary users of the data, such as the New Jersey Department of Environmental Protection (NJDEP), are responsible for evaluating the data using quality criteria appropriate for their use and/or decision making process.

Table 1-1: List of Primary Data Users

Central Sewage Treatment Facility	Hydraulically Connected CSO Municipalities and Permittees
Passaic Valley Sewage Commission (PVSC)	Paterson City ¹ ; Newark City ¹ ; Kearny Town ¹ ; Harrison Town ¹ ; East Newark Borough ¹ ; Bayonne MUA ¹ ; Jersey City MUA ¹ ; North Bergen MUA ¹

Middlesex County Utilities Authority (MCUA)	Perth Amboy City ¹

¹ Owns CSO Permitted outfalls discharging to modeled receiving waters. ²Municipality with CSOs within their limits but not a permit holder

1.3 Decision Makers

NJDEP has decision-making authority for the selection and application of the typical year. The Program Manager for PVSC is ultimately responsible for all technical, financial, and resource-related elements of the Program and is the main contact for interagency communications. Any changes made to the typical year selection as outlined in this Report will be reported in writing for signatory approval and amendments to the Report will be submitted, as necessary.

1.4 Problem Definition and Background

The NJ CSO Group was originally formed to work cooperatively to fulfill the requirements of the last CSO General Permit. The group was recently expanded to include more permittees that discharge to the tidally connected waterbodies in the NY/NJ Harbor Estuary. Member utilities provide service to multiple municipalities, and the interrelationships are numerous and varied as shown on **Figure 1-1**.

Figure 1-1: Participating NJCSO Group Members and Associated Central Sewage Treatment Facilities

For example:

- The utilities responsible for providing treatment typically do not have permitted CSOs, which are the responsibility of the municipalities;
- The municipalities with permitted CSOs may not be able to reduce their discharges without the treatment utility modifying its treatment and/or conveyance system;
- Certain municipalities own and operate their own combined sewer systems, interceptors, CSO control facilities, and pumping stations, while others do not own their collection systems; and
- Combinations of utilities and municipalities may jointly own force mains, pumping stations, and other appurtenances but remain independently permitted by the State of New Jersey.

Because of these complex interrelationships, the NJ CSO Group elected to have PVSC lead the technical work required for CSO permit compliance relative to the selection of a typical year. Participating members may use the results generated by the typical year analysis for assessing CSO impacts and potential mitigation strategies.

1.5 Annual Precipitation Trend 1948-2015

Average U.S. precipitation has increased since 1900, but there are regional differences, with some areas having larger increases, and others, decreases. Local climate change should be considered when selecting appropriate data records for the typical period analysis.

Daily Precipitation data from Newark Liberty International Airport were obtained from the National Oceanic and Atmospheric Administration (NOAA) from 1948 through 2015 to evaluate precipitation trend.

Figure 1-2 shows annual precipitation depth from 1948 to 2015. An average straight trend line using sum of least squares is also shown in the figure for characterizing long-term precipitation pattern. During 1948 through 2015, annual precipitation depth ranges from 26.9 to 69.91 inches, with the driest year in 1963 and the wettest year in 2011. The figure splits to show the trend line change from 1948 to 1970 contrasted to 1970 to 2015. From 1948 to 1970 shows a declining pattern with an approximate change of -0.337 inch per year. From 1970 to 2015 shows an inclining pattern with an approximate change of +0.032 inch per year. The latter trend line is more relevant to present day. Therefore it is determined that the typical period for the LTCP to be selected based on statistical analysis of precipitation records in recent 46 years (i.e., 1970-2015).

Figure 1-2: Annual Precipitation Depth at Newark Liberty International Airport

1.6 Methodology of Typical Year Selection

The typical hydrologic year is selected to provide representative and unbiased approximations of expected conditions in terms of both averages and historical variability. Representativeness is assessed using objective criteria for each of the ambient factors (i.e., river flow and precipitation). As indicated in the previous section, the selection of the typical hydrologic period is based on the historical records in the past 46 years from 1970 through 2015.

The following datasets are used for the analysis of the typical hydrologic period:

- Hourly precipitation data for the National Climate Data Center gauge at Newark Liberty International Airport for 1970 – 2015 is used for analyzing individual rainfall event and event characteristics.
- Daily precipitation data for the National Climate Data Center gauge at Newark WSO Airport for 1970 – 2015 is used for analyzing annual and seasonal precipitation amounts.

The EPA's CSO Control Policy (1994) identifies two general approaches to attainment of water quality standards (WQS): the demonstration approach and the presumption approach.

Under the demonstration approach, the municipality would be required to successfully demonstrate compliance with each of the following criteria (II.C.4.b):

- i. the planned control program is adequate to meet WQS and protect designated uses, unless WQS or uses cannot be met as a result of natural background conditions or pollution sources other than CSOs;*
- ii. the CSO discharges remaining after implementation of the planned control program will not preclude the attainment of WQS or the receiving waters' designated uses or contribute to their impairment. Where WQS and designated uses are not met in part because of natural background conditions or pollution sources other than CSOs, a total maximum daily load, including a wasteload allocation, a load allocation or other means should be used to apportion pollutant loads;*
- iii. the planned control program will provide the maximum pollution reduction benefits reasonably attainable; and*
- iv. the planned control program is designed to allow cost-effective expansion or cost-effective retrofitting if additional controls are subsequently determined to be necessary to meet WQS or designated uses.*

Under the presumption approach, controls adopted in the LTCP should be required to meet one of the following criteria (II.C.4.a):

- i. No more than an average of four overflow events per year, provided that the permitting authority may allow up to two additional overflow events per year. For the purpose of this criterion, an overflow event is one or more overflows from a CSS as the result of a precipitation event that does not receive the minimum treatment specified...[see definition of minimum treatment, below]; or*
- ii. The elimination or the capture for treatment of no less than 85% by volume of the combined sewage collected in the CSS during precipitation events on a system-wide annual average basis; or*
- iii. The elimination or removal of no less than the mass of the pollutants identified as causing water quality impairment through the sewer system characterization, monitoring, and modeling effort for the volumes that would be eliminated or captured for treatment under paragraph ii above.*

Criteria used in this typical year analysis were developed based on requirements listed in the presumption approach and the demonstration approach, and potential operational and maintenance considerations for CSO control facility.

Key criteria parameters used in the evaluation are listed in **Table 1-2**. Each parameter is given a weighting factor to describe the individual importance on the averageness of the analyzed time period.

- Annual precipitation depth: it is the total precipitation depth in a specific year. This parameter is important in evaluating annual overflow volume and potential storage volume needed for CSO controls.
- Number of events with rainfall depth equal to or greater than 0.2 inch: this parameter is selected because a previous study indicates that for a storm event of 0.2 inch, 40% of the CSOs are activated in the municipalities tributary to the main interceptor and 25% of the CSOs in the City of Bayonne are activated. As a result, 0.2 inch of total rainfall volume provides a conservative metric for defining a system overflow event.
- Number of events with rainfall depth equal to or greater than 0.1 inch: it is recommended a rainfall trigger of 0.1 inch be used in the analysis. Such rainfall trigger is used to indicate potential start of surface runoff and trigger for overflow in some of the systems.
- The 5th largest storm volume: this is the 5th largest storm by volume in a specific year. This parameter is important for designing maximum storage capacity for potential presumptive approach. One of the presumption approach requires “*No more than an average of four overflow events per year*” which means that the system would need to retain the 5th largest storm to avoid overflows more than four events.
- Rainfall volume for 85% captured: this is the individual precipitation depth that the collection system should be able to capture to achieve an annual goal of at least 85% capture of wet weather volumes. This parameter is also important for determining maximum storage volume or WWTP capacity for potential presumptive approach. Another requirement of the presumption approach indicates “*The elimination or the capture for treatment of no less than 85% by volume of the combined sewage collected in the CSS during precipitation events on a system-wide annual average basis*”. This parameter is estimated by assigning a precipitation depth (named “R85”) to a specific year, rainfall events with precipitation depth equal to or less than this value (R85) will be completely captured, and rainfall events with precipitation depth greater than this value (R85) will be captured up to the assigned value. The ratio of the total captured precipitation depth to the total annual precipitation depth in the year should be 0.85. Calculation of R85 is an iterative process.
- Number of back-to-back rainfall events: this parameter is important for determining antecedent conditions and maximum storage volume or WWTP capacity. If the next rainfall event’s starting time is within 24 hours of the previous rainfall event’s ending time, these two rainfall events are considered as back-to-back rainfall events. This parameter could impact potential CSO facility operations.

- Maximum peak intensities of the 5th largest storm and less: this is the maximum of the peak precipitation intensities of rainfall events that is smaller than the fourth largest storm by volume in a specific year. This parameter is important for determining the sizing of conveyance pipes, diversions, regulators, pumps, etc. The system would need to be able to pass this peak intensity to avoid overflows at the 5th largest storm event.
- Number of storm events with return frequency equal to or greater than 1-year: this parameter is to calculate the total storm event number that has return frequencies of 1-year and above. This parameter is important for determining extremely large storms. The return frequency is determined by comparing precipitation depth to the NOAA's precipitation frequency estimates for Newark CSO Airport (**Table 1-3 & Figure 1-3**). **Figure 1-3** shows example plots of three rainfall events with precipitation frequency more than 1-year. The three events have different durations, the 5 to 10-year event is above 5-year frequency in duration 4-9 hour, the 2-year event is above 2-year frequency in duration 17-24 hour, and the 1-year event has 1-year frequency in duration 4-6 hour.
- Average Rainfall Duration: this parameter is important for determining storage capacity. The longer the duration of a rainfall event the more likely the system reaches its capacity and start overflowing.
- Average Rainfall Intensity: this parameter is important for determining storage capacity of the system including pipes, regulators, diversions, etc.

Table 1-2: Typical Hydrologic Year Ranking Parameters

Criteria Parameter	Description / Importance	Weighing Factor
Annual rainfall depth	Impacting annual overflow volume and storage volume	30%
# of events with rainfall depth ≥ 0.2 in	Rainfall depth to trigger overflow in existing system	10%
# of events with rainfall depth ≥ 0.1 in	Rainfall depth to trigger surface runoff	5%
5 th largest storm volume	Determining max storage capacity or WWTP capacity	5%
Rainfall volume for 85% captured	Determining max storage capacity or WWTP capacity	5%
# of back-to-back rainfall events	Determining antecedent conditions and potential storage facility operation	10%
Maximum peak intensities of the 5 th largest storm and less	Determining the sizing of conveyance pipes, diversions, regulators, pumps, etc.	5%
# of storms with return frequency ≥ 1 -year	Extremely large storms to be avoid	5%
Average Rainfall Duration	Determining storage capacity	15%
Average Rainfall Intensity	Determining storage capacity including pipes, regulators, diversions, etc.	10%

Figure 1-3: Examples of Three Rainfall Events with Precipitation Frequency above 1-year

Section 2 Typical Year Analysis

2.1 Statistical Analysis 1970-2015

The 46-year hourly precipitation data (1970 - 2015) from the Newark WSO Airport was analyzed to evaluate all individual rainfall events in the period. An inter-event time (IET) of 6 hours (i.e. minimum dry time of 6 hours between rainfall events) was used to differentiate between individual rainfall events. All rainfall events for the data period were analyzed for duration, inter-event duration, total rainfall amount, as well as maximum rainfall intensities.

A total of 4,812 rainfall events were counted for the period of 1970 – 2015 (3022 events with a total depth ≥ 0.1 inch). Events with a total precipitation depth equal to or greater than 0.1 inch are used for further analysis. **Table 2-1** summarizes rainfall events on an annual basis for annual rainfall depth, number of events above 0.2 inch, number of events above 0.1 inch, the 5th largest storm volume, rainfall volume for 85% captured, number of back-to-back rainfall events, maximum peak intensity of 5th largest and smaller events, number of events with return frequency of 1-year and above, average rainfall duration, and average rainfall intensity. The average of the 46 years is shown at the end of the table for each criteria parameter.

Table 2-1: Annual Rainfall Statistics 1970-2015

Year	Annual Rainfall (in)	# of Events > =0.2" Rainfall Depth	# of Events > =0.1" Rainfall Depth	5th Largest Storm (in)	Rainfall Volume for 85% Captured (in)	# of back-to-back events	Maximum Peak Intensity of 5th Largest & Smaller	# of Storms with Return Freq > 1-yr	Average Rainfall Duration (hr)	Average Rainfall Intensity (in/hr)
1970	34.39	50	64	1.07	0.77	17	0.98	0	9.36	0.080

Average (1970-2015)	46.28	51.2	65.7	1.72	1.35	10.54	0.90	2.2	10.9	0.081

2.2 Ranking Analysis

Ranking analysis was performed by the following steps:

Step 1. Calculation of absolute deviation from average values

(Using 1970 annual rainfall as an example)

Absolute deviation = $\text{abs}(34.39 - 46.28) = 11.89$ in

Step 2. Calculation of relative deviation by dividing the absolute deviation by the average value:

Relative deviation = $11.89 / 46.28 = 0.257$

Step 3: Calculation of weighted deviation score by multiplying the weighting factor (**Table 1-2**) to the relative deviation:

Weighted deviation score = $30\% \times 0.257 = 0.077$

Table 2-2 shows weighted deviation scores for all parameters and years.

Step 4: Calculation of final score by adding the weighted deviation scores of all the ten ranking parameters:

Final score for 1970 =

$0.077 + 0.002 + 0.001 + 0.019 + 0.022 + 0.061 + 0.004 + 0.050 + 0.021 + 0.001 = 0.258$

Table 2-2 shows final scores for all years.

Step 5: Rank the years based on the final scores. The lower the final score, the higher the rank for the hydrologic period (i.e., the closer it is to the average condition).

Figure 2-1 and **Table 2-2** show the ranking results of the 46 years, with a ranking of 1 being the highest and a ranking of 46 being the lowest ranked hydrologic period.

Figure 2-1: Ranking Score of 1970-2015

Table 2-2: Typical Hydraulic Year Ranking Analysis_Deviation Score

Year	Annual Rainfall (in)	# of Events >=0.2" Rainfall Depth	# of Events >=0.1" Rainfall Depth	5th Largest Storm (in)	Rainfall Volume for 85% Captured (in)	# of back-to-back events	Maximum Peak Intensity of 5th Largest & Smaller	# of Storms with Return Freq > 1-yr	Average Rainfall Duration (hr)	Average Rainfall Intensity (in/hr)	Final Score	Rank

2.3 Top 20 Ranked Years

Table 2-3 summarizes top 20 ranked years based on the ranking analysis. It was decided that a more recent period be used for the PVSC CSO LTCP study to reflect recent climate conditions. It was also determined that the typical year should be selected from years with annual precipitation depth greater than the average value (highlighted with green background in **Table 2-3**) to be more conservative. Therefore the following five years are the top years to be considered for typical year selection:

- 1: 2004
- 2: 2014
- 3: 1973
- 4: 2008
- 5: 2006

Table 2-3: Top 20 Ranked Years

Preliminary Rank	Year	Deviation Score	Annual Rainfall (in)	# of Events $\geq 0.2"$ Rainfall Depth	# of Events $\geq 0.1"$ Rainfall Depth	5th Largest Storm (in)	Rainfall Volume for 85% Captured (in)	# of back-to-back events	Maximum Peak Intensity of 5th Largest & Smaller	# of Storms with Return Freq > 1-yr	Average Rainfall Duration (hr)	Average Rainfall Intensity (in/hr)
Weighing Factor			30%	10%	5%	5%	5%	10%	5%	5%	15%	10%

Table 2-4 summarizes quantity of large rainfall events with return frequencies for the above-mentioned five years.

Table 2-4: Quantity of Rainfall Events above 1-year Return Frequency

Final Rank	Year	Quantity of Rainfall Events with Return Frequency Above				
		1-yr	2-yr	5-yr	10-yr	50-yr
1	2004	2	1			
2	2014	1			1	0
3	1973	2				
4	2008	1	1	1		
5	2006	1		1		1

2.4 Hydrologic and Hydraulic Model Results

A hydrologic and hydraulic (H&H) model was simulated from 1996 to 2015 to include the 20 most recent years. The simulation results were analyzed to verify if the selected typical year yields overflow quantity and volume close to the average conditions. The model used was the PVSC model that was re-calibrated in 2016. This model includes the five CSO communities of Paterson, Newark, East Newark, Kearny and Harrison within PVSC's service area. **Figure 2-2** and **Figure 2-3** show the simulated results for volume of overflows and number of CSO events, respectively.

Figure 2-2: Hydrologic and Hydraulic Model - CSO Volume

Figure 2-3: Hydrologic and Hydraulic Model - Number of CSO Events

The model results show that overflow in 2004 is close to the average conditions: only 1.5% greater than the average for CSO volume and 6.7% greater than the average for CSO event number. Another year that is close to the average conditions in terms of CSO volume and event number is 2014. 2014 is not considered as a good candidate because it has an extremely large storm with 10-year return frequency.

2.5 Recommendations

It is recommended the year 2004 selected as the typical hydrologic year for the CSO LTCP based on ranking analysis and H&H modeling results. The year 2004 was ranked first in the criteria described above and contains a wide range of storms and antecedent conditions, and it has close to an average CSO volume and event number based on the hydrologic and hydraulic model results.

A summary of the parameters and the percent difference is shown below in **Table 2-5**. The top 20 rainfall events (by depth) in 2004 is shown in **Table 2-6**.

Table 2-5: Summary of the Recommended Typical Year - 2004

Parameters	2004
Annual Precipitation*	48.37 in (4.5% greater than average 46.27)
Number of Events ≥ 0.2 " Rainfall Depth	54 (5% greater than average 51.2)
Number of Events ≥ 0.1 " Rainfall Depth	73 (11% greater than average 66)
5 th Largest Storm Volume	1.63 in (5% less than average 1.70)
Rainfall Volume for 85% Capture	1.18 in (12% less than average 1.35)
Back-to-Back Storm Events	12 (14% greater than average 10.5)
Max Peak Intensity of 5 th Largest Storm & Smaller	0.99 in/hr (9.5% greater than average 0.90)
Extreme Storm	1 Year Storm (2) 2 Year Storm (1)
Average Rainfall Duration	10.3 hr (4.8% less than average 10.8)
Average Rainfall Intensity	0.084 in/hr (3.8% greater than average 0.081)

*Note: Includes snowfall.

Table 2-6: Top 20 Rainfall Events by Depth in 2004

2004	Event Start	Duration (hr)	Precipitation Depth (in)	Max Rainfall Intensity (in/hr)	Average Rainfall Intensity (in/hr)	Return Frequency

Introduction

Background and Scope

Hatch Mott MacDonald entered into an agreement with ADS Environmental Services to monitor flow at forty (40) metering locations and to measure rain at three (3) rain gauge located in The City of Elizabeth, New Jersey. The monitoring period began on Saturday, August 22, 2015 and ended on Monday, December 21, 2015. The objectives of this study were to measure rainfall, depth of flow, velocity, and quantify flows.

Monitoring Tasks

Monitoring tasks included:

- Investigating proposed flow-monitoring sites for proper hydraulic conditions
- Investigating proposed rain gauge sites for sufficient exposure and non-excessive wind
- Installing flow monitors and rain gauges
- Precisely measuring pipe geometry
- Manually confirming monitor depth and velocity readings
- Manually confirming rain gauge tipping bucket operation
- QA/QC data for bias and outliers, correcting as necessary
- Flow data analysis

In addition to the flow monitors and rain gauges, the following supplemental instrumentation was installed:

- Two Groundwater Gauges
- Two Tide Gauges
- Thirteen Tide Gate Limit Switches

Equipment

Flow Monitoring Equipment

The **ADS FlowShark Triton** monitor was selected for this project. This flow monitor is an area velocity flow monitor that uses both the Continuity and Manning's equations to measure flow.

The ADS FlowShark Triton monitor consists of data acquisition sensors and a battery-powered microcomputer. The microcomputer includes a processor unit, data storage, and an on-board clock to control and synchronize the sensor recordings. The monitor was programmed to acquire and store depth of flow and velocity readings at 5-minute intervals.

The FS Triton monitor features cross-checking using multiple technologies in each sensor for continuous running of comparisons and tolerances. The FS Triton monitor can support two (2) sets of sensors. The sensor options used for this project were:

The Peak Combo Sensor installed at the bottom of the pipe includes three types of data acquisition technologies.

The **up looking ultrasonic depth** uses sound waves from two independent transceivers to measure the distance from the sensor upward toward the flow surface; applying the speed of sound in the water and the temperature measured by sensor to calculate depth.

The **pressure depth** is calculated by using a piezo-resistive crystal to determine the difference between hydrostatic and atmospheric pressure. The pressure sensor is temperature compensated and vented to the atmosphere through a desiccant filled breather tube.

To obtain **peak velocity**, the sensor sends an ultrasonic signal at an angle upward through the widest cross-section of the oncoming flow. The signal is reflected by suspended particles, air bubbles, or organic matter with a frequency shift proportional to the velocity of the reflecting objects. The reflected signal is received by the sensor and processed using digital spectrum analysis to determine the peak flow velocity.

The Surface Combo Sensor installed at the top of the pipe features four measurement technologies.

The sensor uses four independent ultrasonic transceivers to measure the distance from the face of the transceiver housing to the water surface then applies the speed of sound in air & the sensor measured temperature to the elapsed time between transmitting and receiving the ultrasonic waves to calculate the **ultrasonic depth**.

To measure velocity, transmitted ultrasonic sound waves is reflected by disturbances on the flow surface and the resulting echo is detected by the sensor. The **surface velocity** is then calculated based upon the Doppler shift of the reflected sound waves.

Under full pipe or surcharge conditions:

The **surcharge pressure depth** is calculated by using a piezo-resistive crystal to determine the difference between hydrostatic and atmospheric pressure. The pressure sensor is temperature compensated and vented to the atmosphere through a desiccant filled breather tube.

The **surcharge peak velocity** is calculated by using ultrasounds to detect frequency shifts of particles in the flow. An ultrasonic signal is sent at an angle upward through the widest cross-section of the oncoming flow where the signal is reflected by suspended particles, air bubbles, or organic matter in the flow. A digital spectrum analysis is used to determine the Doppler shift of the reflected sound waves.

The Ultrasonic Level Sensor installed at the top of the pipe features four measurement technologies.

The sensor uses four independent ultrasonic transceivers to measure the distance from the face of the transceiver housing to the water surface then applies the speed of sound in air & the sensor measured temperature to the elapsed time between transmitting and receiving the ultrasonic waves to calculate the **ultrasonic depth**.

Installation

Installation of flow monitoring equipment typically proceeds in four steps. First, the site is investigated for safety and to determine physical and hydraulic suitability for the flow monitoring equipment. Second, the equipment is physically installed at the selected location. Third, the monitor is tested to assure proper operation of the velocity and depth of flow sensors and verify that the monitor clock is operational and synchronized to the master computer clock. Fourth, the depth and velocity sensors are confirmed and line confirmations are performed.

In pipes up to 42 inches in diameter, the sensors were mounted on expandable stainless steel rings, inserted at least a foot upstream into influent pipes and tightened against the inside walls of the pipes. Influent pipe installations reduce the influences of turbulence and backwater often caused by changes in channel geometry in manholes.

¶¶¶

In pipes larger than 42 inches in diameter, a special installation is made using two sections of the ring installed one to two feet upstream of the pipe/manhole connection; one bolted to the crown of the pipe for the surface combo sensor and the other bolted to the bottom of the pipe (bolts are usually placed just above the water line) to hold the peak combo sensor.

Data Collection, Confirmation, and Quality Assurance

Data collection was done remotely via telemetry by a Data Analyst. Periodically during the monitoring period, field crews visit each monitoring location to verify proper monitor operation and document field conditions. The following quality assurance steps are taken to assure the integrity of the collected data:

Measure power supplies: monitors were powered by dry cell battery packs. Voltages were recorded and battery packs replaced, as necessary. Separate batteries provided back-up power to memory allowing primary batteries to be replaced without loss of data.

Clock synchronization: Field crews synchronized monitor clocks to master clocks.

Confirm depth and velocity readings: Field crews descended into meter manholes to manually measure depths and velocities and compare them meter readings to confirm that they agreed. They also measured silt levels, if any, in the inverts of the pipes. Silt areas were subtracted from flow areas to compute true areas of flow.

Confirm average velocities through cross-sectional velocity profiles: Since ADS velocity sensors measure peak velocity, field crews collected cross-sectional velocity profiles in order to develop a relationship between peak and average velocity in lines that meet the hydraulic criteria.

Confirm flows using V-notched weirs: For monitoring locations where the depth of flow is less than 2.00", flow may be verified by inserting a v-notch weir into the mouth of pipe to directly measure the flow rate. This method requires the field crew to seal and level the weir, wait for it to fill and stabilize, then record the flow rates from the numbers on the weir (gpd). Depth and manually recorded flow rates were then used to calculate the average velocity needed to verify velocity sensor readings.

Upload and Review Data: Data collected from the monitors were uploaded and reviewed by a Data Analyst for completeness, outliers and deviations in the flow patterns, which indicate system anomalies or equipment failure.

Methodology

Flow Quantification Methods

There are two main equations used to measure open channel flow: the **Continuity Equation** and the **Manning Equation**. The Continuity Equation, which is considered the most accurate, can be used if both depth of flow and velocity are available. In cases where velocity measurements are not available or not practical to obtain, the Manning Equation can be used to estimate velocity from the depth data based on certain physical characteristics of

the pipe (i.e. the slope and roughness of the pipe being measured). However, the Manning equation assumes uniform, steady flow hydraulic conditions with non-varying roughness, which are typically invalid assumptions in most sanitary sewers. The Continuity Equation was used exclusively for this study.

Continuity Equation

The Continuity Equation states that the flow quantity (Q) is equal to the wetted area (A) multiplied by the average velocity (V) of the flow.

$$Q = A * V$$

This equation is applicable in a variety of conditions including backwater, surcharge, and reverse flow.

•••

•••

Flow Classifications

Flow classifications can be determined using factors such as, varying flow cross-sections, fluctuating flow rates, the presence of surface waves and erratic flows.

Ideal Uniform Flows remain steady throughout the cross-section of the line whereas **Gradually Varied Flows**, as seen in drawdown or backwater, change slowly as we move upstream and/or downstream in the line.

When flow rates remain constant over a period of time, they are classified as having **Steady Flow**; if not, they have **Unsteady Flow**.

The speed of surface waves versus that of the flow can be subcategorized to 3 groups: **supercritical**, **subcritical**, and **transitional** (changing from sub to supercritical). The Froude Number (flow speed divided by surface wave speed) is used to characterize these patterns. Froude numbers greater than one are defined as supercritical and Froude numbers less than one are defined as subcritical. Subcritical flow surfaces are always smooth with is good for depth measurements, but may not be good in terms of silt deposition.

Turbulent flow account for 99.9% of all gravity sewer flow even if the flow surface is smooth.

An ideal monitoring location tend to have near-uniform, near-steady, turbulent flow with a smooth surface.

Data Analysis and Presentation

Data Analysis

A flow monitor is typically programmed to collect data at either 15-minute or 5-minute intervals throughout the monitoring period. The monitor stores raw data consisting of (1) the Range (distance from sensor to top of flow) for each active ultrasonic depth sensor, (2) the peak velocity and (3) the pressure depth. When the field personnel collects the data, the air range is converted to depth data based on the pipe height and physical offset (distance from the top of the pipe to the surface of the ultrasonic sensor). The data is imported into ADS's proprietary software and is examined by a data analyst to verify its integrity. The data analyst also reviews the daily field reports and site visit records to identify conditions that would affect the collected data.

Velocity profiles and the line confirmation data developed by the field personnel are reviewed by the data analyst to identify inconsistencies and verify data integrity. Velocity profiles are reviewed and an average to peak velocity ratio is calculated for the site. This ratio is used in converting the peak velocity measured by the sensor to the average velocity used in the Continuity equation. The data analyst selects which ultrasonic pairs and/or depth sensor entity will be used to calculate the final depth information. Silt levels present at each site visit are reviewed and representative silt levels established.

Occasionally the velocity sensor's performance may be compromised resulting in invalid readings sporadically during the monitoring period. This is generally caused by excessive debris (silt) blocking the sensor's crystals, shallow flows (~< 2") that may drop below the top of the sensor or very clear flows lacking the particles needed to measure rate. In order to use the Continuity equation to quantify the flow during these periods, a Sr. Analyst and/or Engineer will use the site's historical pipe curve (depth vs. velocity) data along with valid field confirmations to reconstitute and replace the false velocity recordings with expected velocity readings for a given historical depth along the curve.

Selections for the above parameters can be constant or can change during the monitoring period. While the data analysis process is described in a linear manner, it often requires an iterative approach to accurately complete.

Data Presentation

This type of flow monitoring project generates a large volume of data. To facilitate review of the data, results have been provided in graphical and tabular formats. The flow data is presented graphically in the form of scattergraphs and hydrographs. Tables are provided in daily average format. These tables show the flow rate for each day, along with the daily minimum and maximums, the times they were observed, the total daily flow, and total flow for the month (or monitoring period). The following explanation of terms may aid in interpretation of the tables and hydrographs.

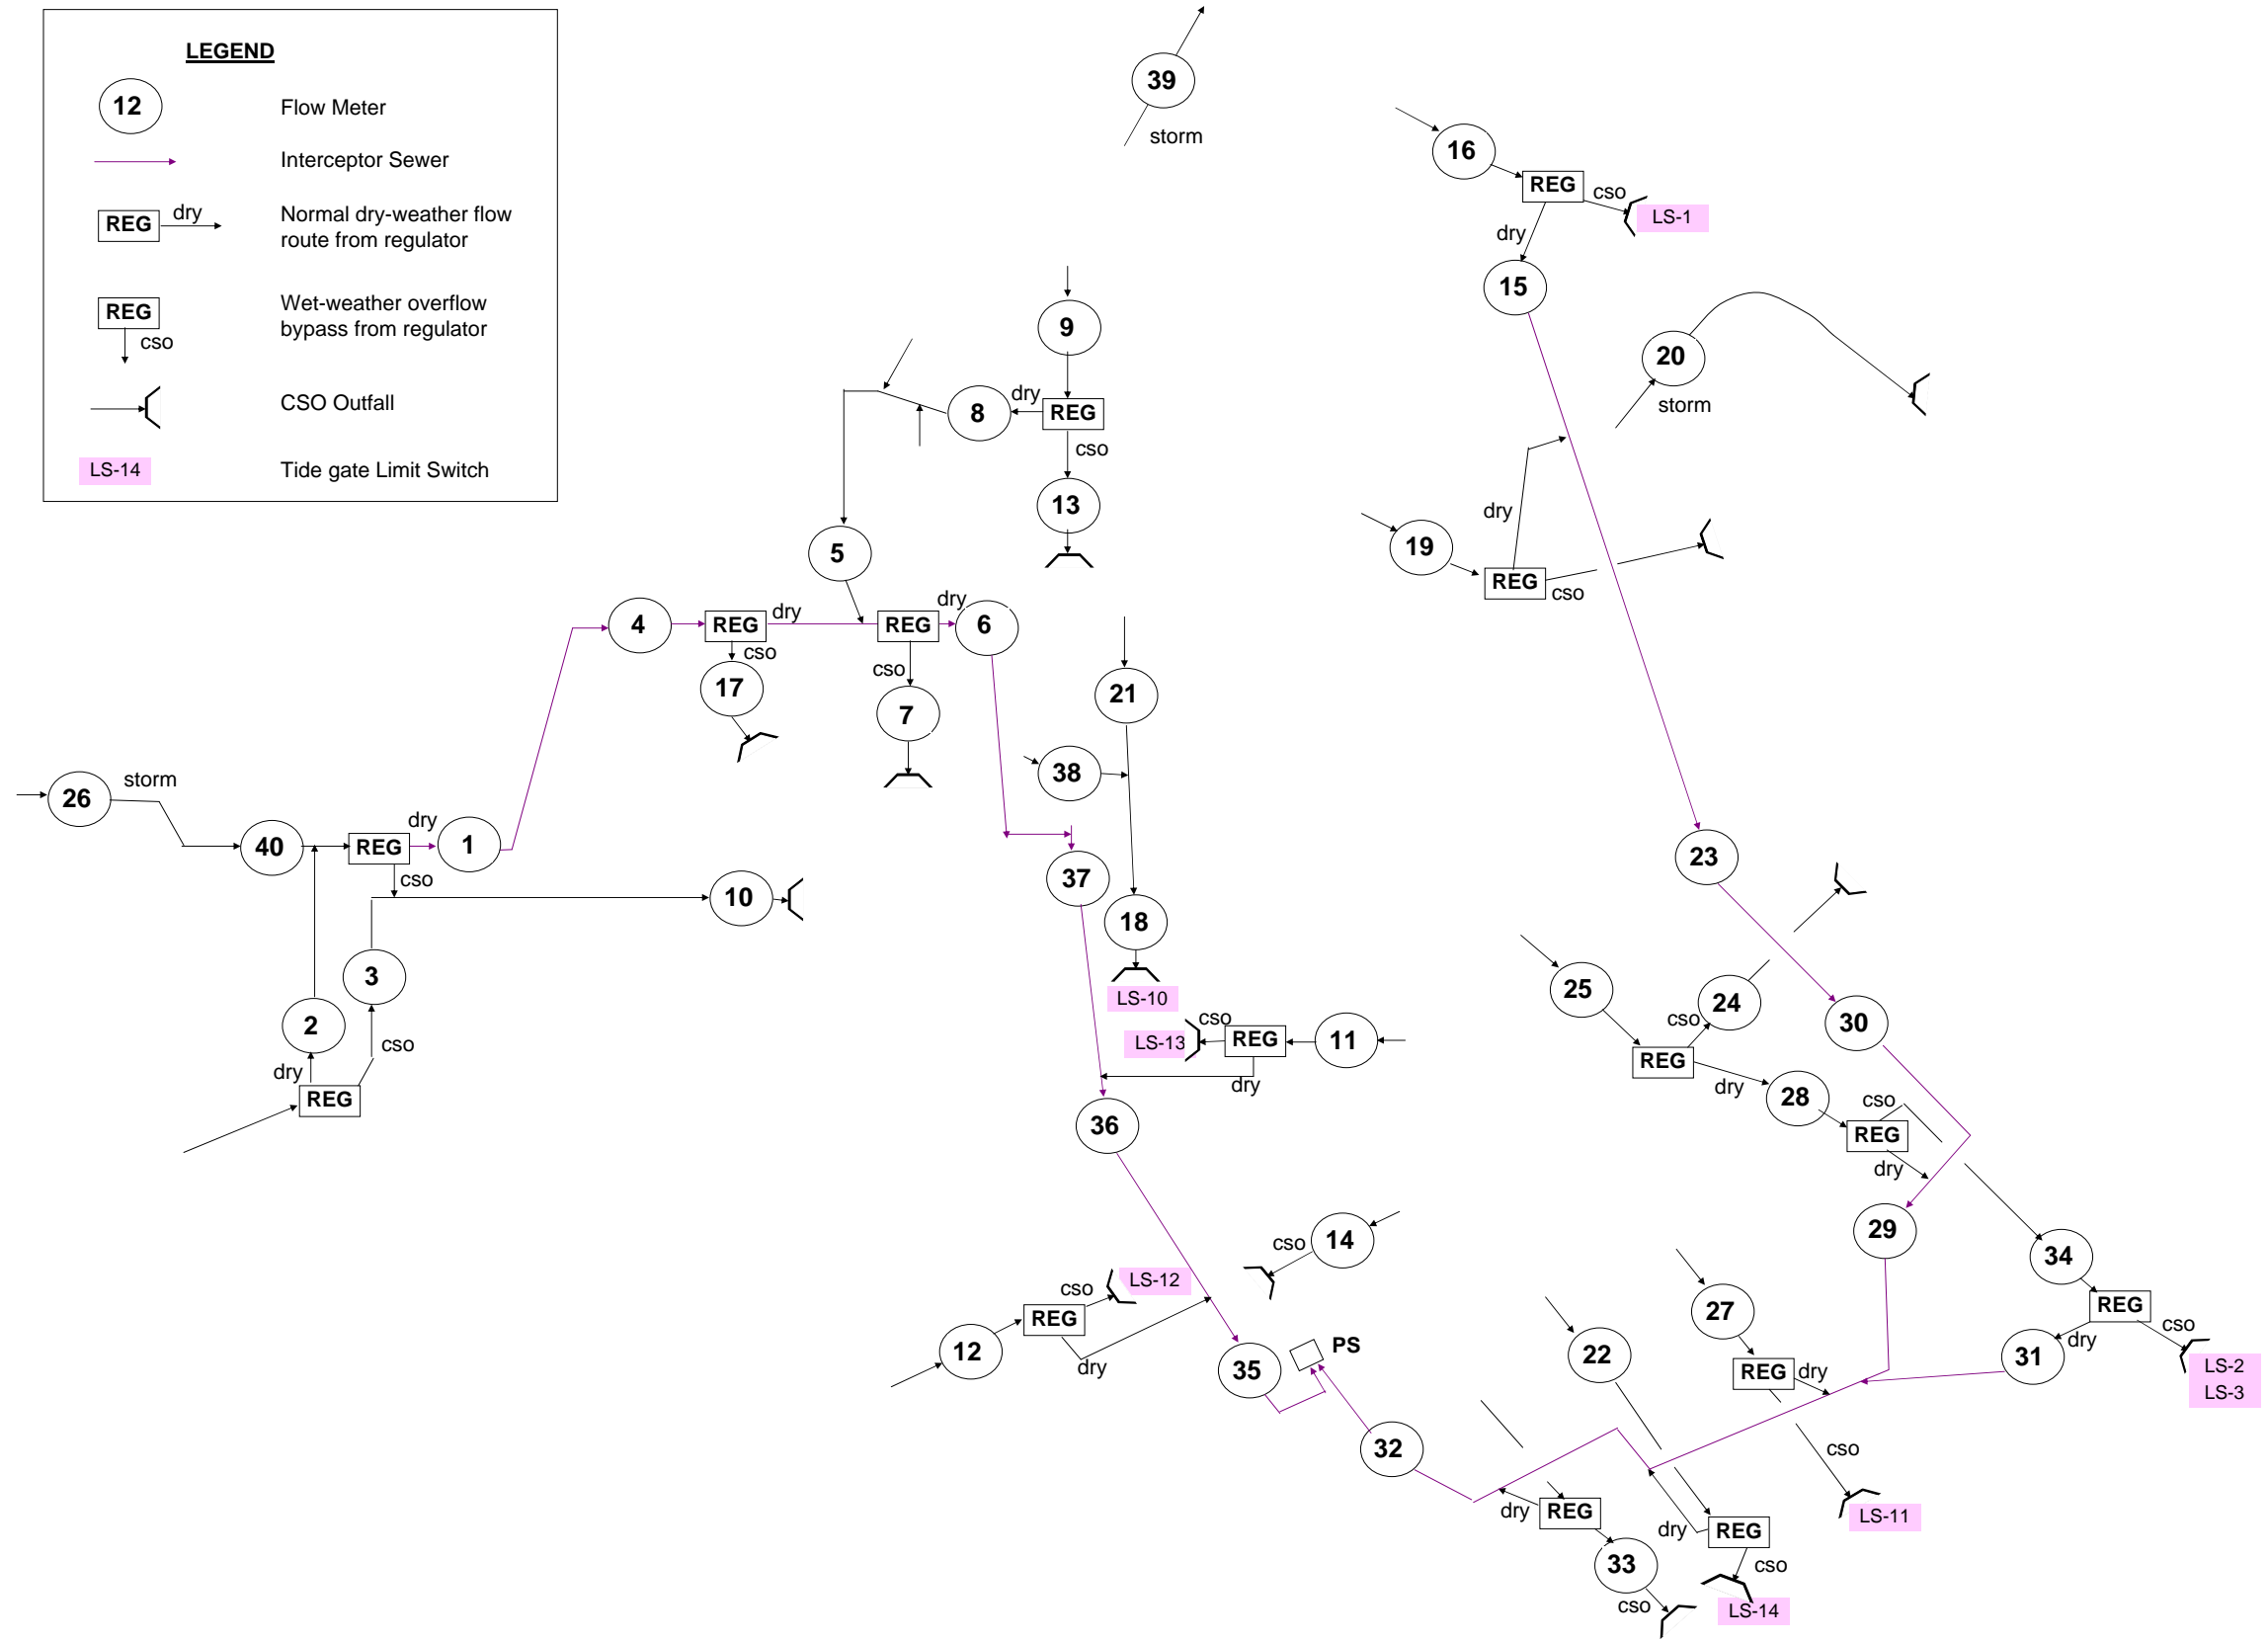

DEPTH - Final calculated depth measurement (in inches)

QUANTITY - Final calculated flow rate (in MGD)

VELOCITY - Final calculated flow velocity (in feet per second)

REPORT TOTAL - Total volume of flow recorded for the indicated time period (in MG)

FLOW SCHEMATIC

Site Commentary

Site Information

M-1	
Pipe Dimensions (in.)	M1 Special (81.00 in H, 57.00 in W)
Silt (in.)	0.00

Overview

M-1 was situated on the Westerly Intercepting Sewer downstream of bypass chamber-Solids/Floatables Control Facility 003A.

Interceptor flow patterns show free flow conditions. Momentary surcharging occurred during the September 30, 2015 rain event.

Observations

Average flow depth, velocity, and quantity data observed during Saturday, August 22, 2015 to Monday, December 21, 2015 , along with observed minimum and maximum data, are provided in the following table.

Observed Flow Conditions			
Item	Depth (in)	Velocity (ft/s)	Quantity (MGD)
Average	19.18	0.45	1.245
Minimum	17.20	0.15	0.315
Maximum	84.41	4.46	70.335
Time of Minimum	9/7/2015 5:15 AM	9/7/2015 5:10 AM	9/7/2015 5:10 AM
Time of Maximum	9/30/2015 2:30 AM	9/30/2015 2:30 AM	9/30/2015 2:30 AM

Based upon the quality and consistency of the observed flow depth and velocity data, the Continuity equation was used to calculate flow rate and quantities during the monitoring period.

Graphical data reports are based on 15-minute averages.

Data Quality

Data uptime observed during the Saturday, August 22, 2015 to the Monday, December 21, 2015 monitoring period is provided in the table below.

Site Commentary

Site Information

M-2	
Pipe Dimensions (in.)	M2 Special (55.76 in H, 50.00 in W)
Silt (in.)	0.00

Overview

M-2 was situated on the combined sewer gravity main downstream of regulator R003B which accepts normal dry weather flow from the regulator.

Typical combined sewer flow patterns were observed in reaction to the range of rainfall events during the study period.

Free flow conditions existed throughout the monitoring period. The flow depth exceeded full pipe during the September 30, 2015 rain event.

Observations

Average flow depth, velocity, and quantity data observed during Saturday, August 22, 2015 to Monday, December 21, 2015 , along with observed minimum and maximum data, are provided in the following table.

Observed Flow Conditions			
Item	Depth (in)	Velocity (ft/s)	Quantity (MGD)
Average	7.63	0.57	0.616
Minimum	5.99	0.28	0.203
Maximum	82.91	4.51	45.545
Time of Minimum	10/1/2015 4:45 AM	10/1/2015 4:45 AM	10/1/2015 4:45 AM
Time of Maximum	9/30/2015 2:30 AM	9/30/2015 2:25 AM	9/30/2015 2:25 AM

Based upon the quality and consistency of the observed flow depth and velocity data, the Continuity equation was used to calculate flow rate and quantities during the monitoring period.

Graphical data reports are based on 15-minute averages.

Data Quality

Data uptime observed during the Saturday, August 22, 2015 to the Monday, December 21, 2015 monitoring period is provided in the table below.

Percent Uptime	
Depth (in)	100
Velocity (ft/s)	100
Quantity (MGD)	100

Site Commentary

Site Information

M-3	
Pipe Dimensions (in.)	Circular (59.50 in H)
Silt (in.)	2.00

Overview

M-3 was situated on the combined sewer overflow from regulator R003A which discharges through monitoring site M-10 to CSO-003 on the Elizabeth River. M-3 was located just downstream of the regulator. The flow monitor was re-located to this location from the combined sewer gravity main on September 1, 2015.

Flow was negligible during dry weather periods, with expected overflow activity in response to rainfall events.

Backwater conditions were evident during all overflow events.

The flow level exceed full pipe during the September 30, 2015 overflow event.

Observations

Average flow depth, velocity, and quantity data observed during Tuesday September 1, 2015 to Monday, December 21, 2015 , along with observed minimum and maximum data, are provided in the following table.

Observed Flow Conditions			
Item	Depth (in)	Velocity (ft/s)	Quantity (MGD)
Average	4.76	0.00	0.014
Minimum	3.39	0.00	0.000
Maximum	80.83	0.80	9.825
Time of Minimum	9/4/2015 7:25 PM	9/1/2015 7:55 PM	9/1/2015 7:55 PM
Time of Maximum	9/30/2015 2:30 AM	9/30/2015 4:35 AM	9/30/2015 2:25 AM

Based upon the quality and consistency of the observed flow depth and velocity data, the Continuity equation was used to calculate flow rate and quantities during the monitoring period.

Graphical data reports are based on 15-minute averages.

Data Quality

Data uptime observed during the Tuesday, September 1, 2015 to the Monday, December 21, 2015 monitoring period is provided in the table below.

Percent Uptime	
Depth (in)	99
Velocity (ft/s)	99
Quantity (MGD)	99

Site Commentary

Site Information

M-4	
Pipe Dimensions (in.)	M4 Special (77.50 in H, 58.75 in W)
Silt (in.)	2.00

Overview

M-4 was situated on the Westerly Intercepting Sewer upstream of regulator R041. Normal dry weather flow from R041 discharges to the Westerly Intercepting Sewer upstream of regulator R005; wet weather overflows discharge through M-17 to CSO-041 on the Elizabeth River.

Interceptor flow patterns show backwater conditions in response to rainfall events.

Surcharging occurred during the September 30, 2015 and October 28, 2015 events.

Observations

Average flow depth, velocity, and quantity data observed during Saturday, August 22, 2015 to Monday, December 21, 2015 , along with observed minimum and maximum data, are provided in the following table.

Observed Flow Conditions			
Item	Depth (in)	Velocity (ft/s)	Quantity (MGD)
Average	15.10	0.99	2.101
Minimum	11.00	0.54	0.802
Maximum	93.14	4.19	63.675
Time of Minimum	9/2/2015 3:50 AM	12/14/2015 8:40 PM	9/7/2015 5:25 AM
Time of Maximum	9/30/2015 2:35 AM	9/30/2015 2:25 AM	9/30/2015 2:25 AM

Based upon the quality and consistency of the observed flow depth and velocity data, the Continuity equation was used to calculate flow rate and quantities during the monitoring period.

Graphical data reports are based on 15-minute averages.

Data Quality

Data uptime observed during the Saturday, August 22, 2015 to the Monday, December 21, 2015 monitoring period is provided in the table below.

Percent Uptime	
Depth (in)	100
Velocity (ft/s)	100
Quantity (MGD)	100

Site Hydraulics:	SMOOTH FLOW		Manhole Material / Condition:	Concrete	Fair
			Active Drop Connections?		
Upstream Input: (L/S, P/S)			Pipe Material / Condition:	Brick / Concrete	Parged
Upstream Manhole:			Mini System Character:	COMMERCIAL	
Downstream Manhole:			Telephone Information:		
Depth of Flow (Wet Dof):	14 +/-	0.5	Access Pole #:	N/A	
Range (Air Dof):	+/-		Distance From Manhole:	N/A Feet	
Peak Velocity:	1.28	fps	Road Cut Length:	N/A Feet	
Silt:	0.25	Inches	Trench Length:	N/A Feet	

Other Information:
40°40'13.0"N 74°13'10.0"W

Installation Information		Backup	Yes	No	?	Distance
Installation Type:	Doppler Special Installation	Trunk				
Sensors / Devices:	CS4 & CS5 SENSORS	Lift/Pump Station				
Surcharge Height:	10 Feet	WWTP				
Rain Gauge Zone:		Other				

Additional Site Information / Comments:
CS4 SN 09644 CS5 SN 05017 EGG SHAPED PIPE

Site Commentary

Site Information

M-5	
Pipe Dimensions (in.)	M5 Special (65.00 in H, 46.25 in W)
Silt (in.)	0.00

Overview

M-5 was situated on the combined sewer gravity main which ties to the Westerly Interceptor Sewer downstream of regulator R041 and upstream of regulator R005. Normal dry weather flow from R005 on the Westerly Intercepting Sewer discharges upstream of M-6; wet weather overflows discharge through M-7 to CSO-005 on the Elizabeth River.

Interceptor-type flow patterns show backwater conditions in response to rainfall events.

Observations

Average flow depth, velocity, and quantity data observed during Saturday, August 22, 2015 to Monday, December 21, 2015 , along with observed minimum and maximum data, are provided in the following table.

Observed Flow Conditions			
Item	Depth (in)	Velocity (ft/s)	Quantity (MGD)
Average	8.20	1.91	1.516
Minimum	5.74	0.72	0.596
Maximum	55.44	3.52	16.774
Time of Minimum	9/29/2015 4:15 AM	10/28/2015 5:10 PM	10/10/2015 4:35 AM
Time of Maximum	9/30/2015 2:20 AM	12/17/2015 12:10 PM	9/30/2015 2:25 AM

Based upon the quality and consistency of the observed flow depth and velocity data, the Continuity equation was used to calculate flow rate and quantities during the monitoring period.

Graphical data reports are based on 15-minute averages.

Data Quality

Data uptime observed during the Saturday, August 22, 2015 to the Monday, December 21, 2015 monitoring period is provided in the table below.

Percent Uptime	
Depth (in)	100
Velocity (ft/s)	100
Quantity (MGD)	100

Site Commentary

Site Information

M-6	
Pipe Dimensions (in.)	Circular (27.00 in H)
Silt (in.)	4.00

Overview

M-6 was situated on the Westerly Intercepting Sewer downstream of regulator R005.

Interceptor flow patterns show backwater conditions and significant surcharging in response to rainfall events.

Observations

Average flow depth, velocity, and quantity data observed during Saturday, August 22, 2015 to Monday, December 21, 2015 , along with observed minimum and maximum data, are provided in the following table.

Observed Flow Conditions			
Item	Depth (in)	Velocity (ft/s)	Quantity (MGD)
Average	19.39	2.46	3.578
Minimum	11.56	0.13	0.307
Maximum	133.65	3.32	7.754
Time of Minimum	12/20/2015 10:30 AM	10/28/2015 10:50 PM	10/28/2015 10:50 PM
Time of Maximum	9/30/2015 2:20 AM	12/1/2015 5:25 AM	12/1/2015 5:25 AM

Based upon the quality and consistency of the observed flow depth and velocity data, the Continuity equation was used to calculate flow rate and quantities during the monitoring period.

Graphical data reports are based on 15-minute averages.

Data Quality

Data uptime observed during the Saturday, August 22, 2015 to the Monday, December 21, 2015 monitoring period is provided in the table below.

Percent Uptime	
Depth (in)	100
Velocity (ft/s)	100
Quantity (MGD)	100

Site Commentary

Site Information

M-7	
Pipe Dimensions (in.)	M7 Special (57.00 in H, 80.00 in W)
Silt (in.)	0.00

Overview

M-7 was situated on the combined sewer overflow main from regulator R005 which discharges to CSO-005 on the Elizabeth River. M-7 was located just upstream of the Solids/Floatables Control Facility for CSO-005.

Flow was negligible during dry weather periods, with expected overflow activity in response to rainfall events.

Conditions appeared to be in free flow during some overflow events, while others exhibited some degree of backwater.

The flow level exceed full pipe during the October 28, 2015 overflow event.

Observations

Average flow depth, velocity, and quantity data observed during Saturday, August 22, 2015 to Monday, December 21, 2015 , along with observed minimum and maximum data, are provided in the following table.

Observed Flow Conditions			
Item	Depth (in)	Velocity (ft/s)	Quantity (MGD)
Average	3.74	0.03	0.171
Minimum	0.73	0.00	0.000
Maximum	63.02	2.70	42.563
Time of Minimum	12/20/2015 12:00 AM	8/22/2015 12:00 AM	8/22/2015 12:00 AM
Time of Maximum	10/28/2015 5:10 PM	10/28/2015 5:15 PM	10/28/2015 5:15 PM

Based upon the quality and consistency of the observed flow depth and velocity data, the Continuity equation was used to calculate flow rate and quantities during the monitoring period.

Graphical data reports are based on 15-minute averages.

Data Quality

Data uptime observed during the Saturday, August 22, 2015 to the Monday, December 21, 2015 monitoring period is provided in the table below.

Percent Uptime	
Depth (in)	100
Velocity (ft/s)	100
Quantity (MGD)	100

Site Commentary

Site Information

M-8	
Pipe Dimensions (in.)	Circular (30.25 in H)
Silt (in.)	6.00

Overview

M-8 was situated on the combined sewer gravity main which conveys normal dry weather flow from regulator R036. M-8 was upstream of M-5 and the Westerly Intercepting Sewer.

Interceptor-type flow patterns show backwater conditions and significant surcharging in response to rainfall events.

Observations

Average flow depth, velocity, and quantity data observed during Saturday, August 22, 2015 to Monday, December 21, 2015 , along with observed minimum and maximum data, are provided in the following table.

Observed Flow Conditions			
Item	Depth (in)	Velocity (ft/s)	Quantity (MGD)
Average	14.51	1.07	1.129
Minimum	11.96	0.69	0.556
Maximum	116.79	2.80	7.761
Time of Minimum	11/18/2015 2:40 AM	10/17/2015 3:20 AM	10/17/2015 3:20 AM
Time of Maximum	9/30/2015 2:25 AM	9/10/2015 3:10 PM	9/10/2015 3:10 PM

Based upon the quality and consistency of the observed flow depth and velocity data, the Continuity equation was used to calculate flow rate and quantities during the monitoring period.

Graphical data reports are based on 15-minute averages.

Data Quality

Data uptime observed during the Saturday, August 22, 2015 to the Monday, December 21, 2015 monitoring period is provided in the table below.

Percent Uptime	
Depth (in)	100
Velocity (ft/s)	100
Quantity (MGD)	100

Site Commentary

Site Information

M-9	
Pipe Dimensions (in.)	M9 Special (52.25 in H, 41.50 in W)
Silt (in.)	0.00

Overview

M-9 was situated on the combined sewer gravity main upstream of regulator R036. Normal dry weather flow from R036 discharges to the combined sewer main upstream of M-5; wet weather overflows discharge to the combined sewer overflow main upstream of M-13 and CSO-036 on the Elizabeth River.

Typical combined sewer flow patterns were observed in reaction to the range of rainfall events during the study period.

Backwater conditions were evident during most rain events and the flow depth exceeded full pipe during the September 30, 2015 event.

Observations

Average flow depth, velocity, and quantity data observed during Saturday, August 22, 2015 to Monday, December 21, 2015 , along with observed minimum and maximum data, are provided in the following table.

Observed Flow Conditions			
Item	Depth (in)	Velocity (ft/s)	Quantity (MGD)
Average	8.13	0.88	1.037
Minimum	6.05	0.47	0.423
Maximum	84.33	4.00	34.266
Time of Minimum	9/20/2015 4:25 AM	12/13/2015 3:40 AM	9/28/2015 3:35 AM
Time of Maximum	9/30/2015 2:25 AM	9/30/2015 2:25 AM	9/30/2015 2:25 AM

Based upon the quality and consistency of the observed flow depth and velocity data, the Continuity equation was used to calculate flow rate and quantities during the monitoring period.

Graphical data reports are based on 15-minute averages.

Data Quality

Data uptime observed during the Saturday, August 22, 2015 to the Monday, December 21, 2015 monitoring period is provided in the table below.

Percent Uptime	
Depth (in)	100
Velocity (ft/s)	100
Quantity (MGD)	100
